# Double Beta Spectrometers

# Development and installation of the **GERDA** experiment

**GERDA**: the **GER**manium **D**etector **A**rray  
to search for Neutrinoless Double Beta Decay

The **GERDA** project is based  
on using very low background High-Purity-Germanium (HPGe) detectors.

HPGe detector fabricated from germanium enriched in  **$^{76}\text{Ge}$  isotope (up to 86 %)**  
is simultaneously  
**the  $\beta\beta$  decay source and the  $4\pi$  detector.**

The advantages of such type experiments (in comparison with the other types)  
are due to:

- 1) the excellent energy resolution (3 keV at 2 MeV) ,
- 2) the high purity of Ge crystals (very low intrinsic background),
- 3) and the high signal detection efficiency (close to 100%).

Disadvantages:

- 1) not the highest  $\beta\beta$ -transition energy for  $^{76}\text{Ge}$ :  **$Q_{\beta\beta}=2039$  keV**  
(in comparison with the more promising isotopes, such as Mo-100,Nd-150,Ca-48)
- 2) only one characteristic of  $\beta\beta$  decay - **sum energy of two electrons** –  
is possible to detect.

*In spite of these disadvantages, up to now such type of experiments  
are the most sensitive tools in searching for  $(0\nu\beta\beta)$ -decay .*

So far the best limits on  $(0\nu\beta\beta)$ -decay **half-life**  
 $1.9\times 10^{25}$  y and  $1.6\times 10^{25}$  y, which correspond to  $|m_{ee}| < 0.3 - 1.1$  eV,  
have been obtained with HPGe detectors  
in the predecessor experiments **Heidelberg-Moscow & IGEX**  
with using **Enriched Germanium (86% in  $^{76}\text{Ge}$ ,  $Q_{\beta\beta}=2038,5$  keV)**

Moreover, the **part** of H-M Collaboration, after additional data treatment,  
claimed the presence of an excess of events in ROI, which they interpreted  
as the evidence for  $0\nu\beta\beta$  observation  
with the best fit  $T_{1/2} = 1.2\times 10^{25}$  y,  $|m_{ee}| = 0.44$  eV

*H.V. Klapdor-Kleingrothaus, A. Dietz, I.V. Krivosheina, O. Chkvorets, NIM A 522 (2004)*

## Expected sensitivity of the GERDA experiment

### GERDA

will probe **Majorana nature of neutrino**

with sensitivity at

#### GERDA phase I :

with background **0.01 cts / (kg · keV · y)**

► to **scrutinize KKDC result within 1 year**

#### GERDA phase II :

with background **1 cts / (ton · keV · y)**

► to cover **the degenerate neutrino mass**

**hierarchy (  $\langle m_{ee} \rangle < 0.08 - 0.29$  eV )**

#### phase III :

world wide **GERDA –MAJORANA** collaboration

background **0.1 cts / (ton · keV · y)**

► to cover **the inverted neutrino mass hierarchy**

**$\langle m_{ee} \rangle \sim 10$  meV**

To achieve the planned sensitivity the **novel experimental concepts** are developed.

## Main **GERDA** experimental concepts

The main conceptual design of the GERDA experiment is to operate with “naked” **HPGe detectors** (enriched in **Ge-76**) submerged in **high purity liquid argon** supplemented by a **water shield**.

“Naked” detector means the bare Ge crystal without traditional vacuum cryostat.

In the framework of the **extensive R&D program** the main GERDA experimental concepts were proven and the methods of further background reduction were developed and tested.

As it was shown in the IGEX and H-M experiments, the main part of the detector background is due to radioactive contamination in the surrounding materials, including the copper cryostats.

Thus, **minimizing of the support material** mass in the case of using “naked” Ge detectors **should provide considerable (up to 100) reduction of the inner background.**

naking Ge crystals

minimizing  
of the support mass

30g Cu, 6.3g PTFE, 1g Si per detector

**Using of ultra pure LAr** (instead of LN) both **as a cooling media and shielding material**

is the other perspective idea of the GERDA project.

In this case there are several advantages:

- 1) the higher reduction factor of the external background due to **higher LAr density ( $1.4 \text{ g/cm}^3$ );**
- 2) **anti-coincidence with LAr scintillation** should reduce both the inner and external background;

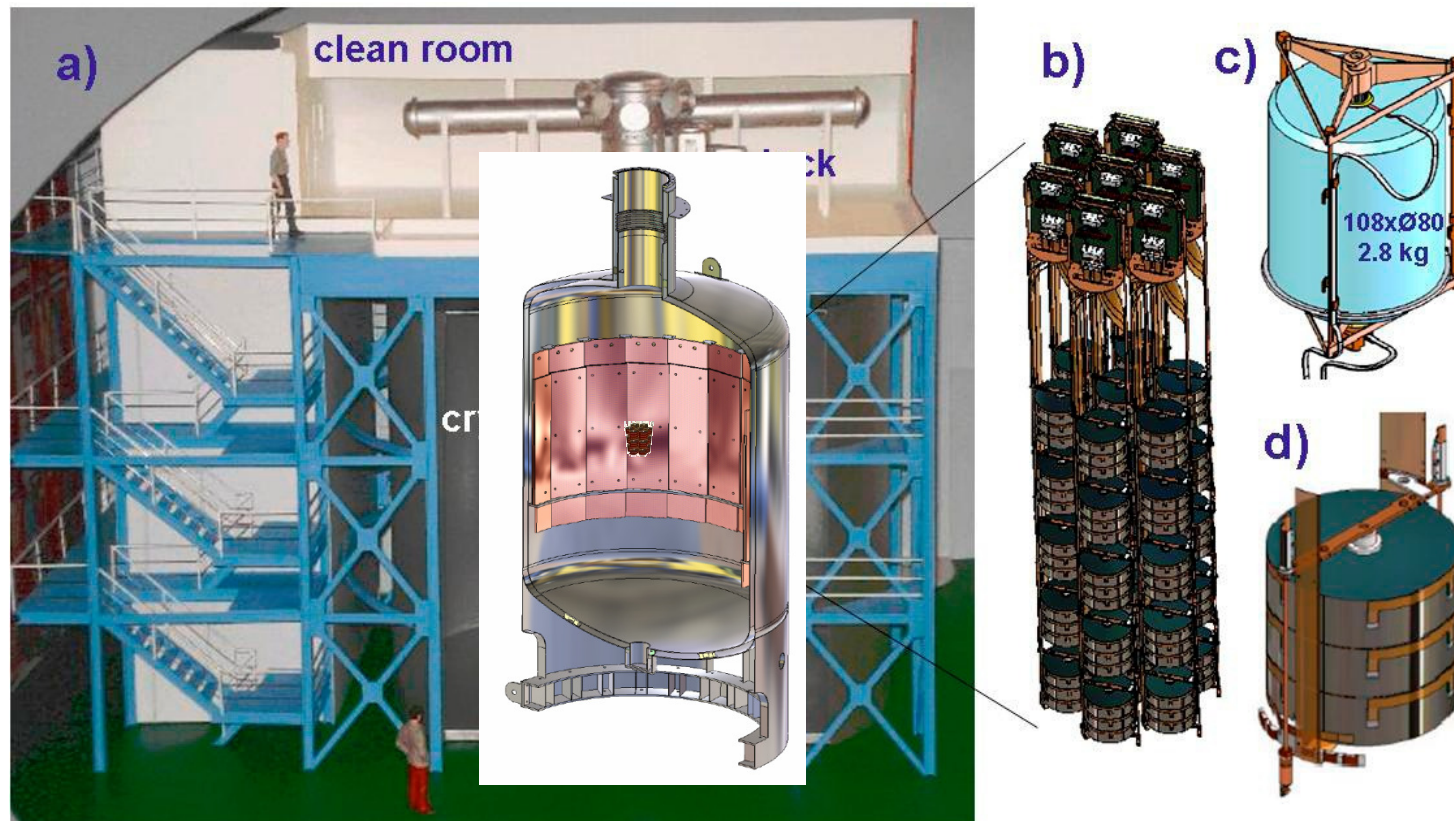

**In the Phase I** all **8 existing and reprocessed enriched detectors** (in total **18 kg of  $^{76}\text{Ge}$** ) from the previous Heidelberg-Moscow and IGEX experiments, and **6 reprocessed natural HPGe detectors** (in total **15 kg of  $^{\text{Nat}}\text{Ge}$** ) from the Genius Test-Facility will be deployed in strings.

**In the Phase II** the new segmented or BeGe detectors ( $>20\text{kg}$  of  $^{76}\text{Ge}$ ) made from recently produced enriched in  $^{76}\text{Ge}$  material will be added. **In total: 40 kg of  $^{76}\text{Ge}$  + 15 kg of  $^{\text{Nat}}\text{Ge}$ .** In addition several detectors from **depleted in  $^{76}\text{Ge}$  material (DepGe)** will be incorporated too.

**A stainless steel cryostat (25 t,  $\text{U/Th} \leq 5 \text{ mBq/kg}$ )** with **internal Cu shield (20 t,  $\text{U/Th} \leq 16 \mu\text{Bq/kg}$ )** will contain **100 tones of LAr,  $^{222}\text{Rn} = \leq 1 \mu\text{Bq/m}^3$** . The cryostat is immersed in a water tank (**590 t of water**).

**The Ge detector array** is made up of individual detector strings and is situated in the central part of the **cryostat**.

## Water tank and Veto system

The ultra-pure water buffer serves as a **gamma and neutron shield** and, instrumented with 66 photomultipliers, as Cherenkov detector **for efficiently vetoing** cosmic muons. Recent simulations show, that an **efficiency of more than 99 %** can be achieved, reducing the muon induced background to a level of  $10^{-5}$  events/(keV · kg · y).

Plastic scintillator panels (20 m<sup>2</sup>, 20 x 2 = 40 modules ) on top of the detector will tag muons which enter the cryostat through the neck with the **vetoing efficiency of about 98 %**.

## General Infrastructure of the GERDA set up

A **cleanroom** and **radon tight lock** on top of the vessel assembly allow to insert and remove individual detector strings without contaminating the cryogenic volume.

## Testing of naked HPGe detectors in LN<sub>2</sub> / LAr

Long-term stability tests (3 HPGe detectors in LN<sub>2</sub>/LAr during 2 years)

Detectors were tested in **liquid Argon** with FWHM  $\sim 2.5$ keV (at 1332keV), and a stable leakage current

**Problems reported from GENIUS-TF** about “limited long-term stability of naked detectors in liquid nitrogen”

*[H.V.Klapdor-Kleingrothaus and I.Krivosheina, NIM A556 (2006) 472]*

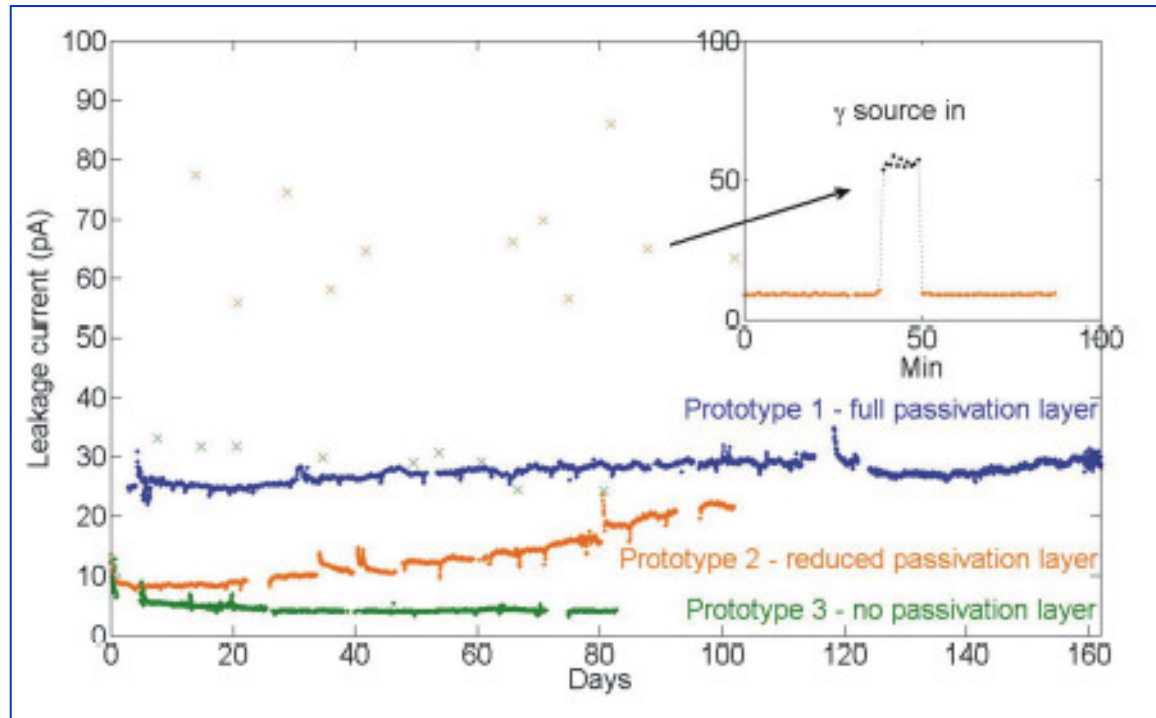

have been overcome by **GERDA**.

**Long term stability for > 1 year.**  
**Detector performances are stable in LAr !**

## The main results achieved during modification of naked HPGe detectors and tests in LAr

1. It was shown that [naked Ge crystals can work directly in liquid argon](#) with the leakage current and energy resolution corresponding to their standard values in the traditional cryostats .
2. Their parameters [are stable during several months](#) after a few dozen cycles of removing and submerging from/in the LAr even after irradiation with intensive gamma sources ([modification without passivation layer](#)).

It shows the feasibility of the overall GERDA project

Construction of the GERDA set up started in 2007 in the INFN Gran Sasso National Laboratory (LNGS), Italy. The “nested type” assembly has **already installed** in the deep underground facility (Hall A) at 3500 m w.e.

## Installation of the GERDA set up

Detector string  
Glove box & lock  
Clean room  
Cryostat &  $\mu$ -veto  
Heat exchanger & pipes

The commissioning of Gerda has started with the cooling of the cryostat on November 2

The **liquid argon filling** will be completed by the end of November.

The **single-string commissioning lock** is scheduled for installation in **February 2010** and **non-enriched detectors will be deployed in the cryostat** as the final step of the commissioning phase.

## R&D for GERDA Phase II

### Additional background reduction techniques

To reach the background level **required for the Phase II**  $10^{-3}$  cts/(keV·kg·y), additional new methods are required mostly to suppress **the intrinsic background** of the detectors.

1. Research and development are carried out to produce **new segmented and BeGe** types of germanium detectors which can **resolve multi-site energy deposits**.
2. Another effective approach is **to discriminate multi-site deposits** from the **pulse shape analysis** of the signal as well as to use **anticoincidence between nearby detectors** assembled in several strings.
3. The novel concept to use the **LAr scintillation light as anti-coincidence signal** for **further background suppression** is developed.

## Novel Ge-detectors with advanced $0\nu\beta\beta$ -signal recognition & background suppression

n-type detectors  
with 18-fold  
segmented  
electrodes

- $0\nu\beta\beta$ : point-like events
- **Bgd**: multi-site or partial energy deposition outside crystal

p-type with small  
readout electrode;  
Similar performance  
with thick-window  
BEGe detectors

SSE/MSE discrimination with BEGe is comparable with 18-fold segmented detector

The pilot setup **Mini-LArGe on the base of LAr scintillator** was successfully operated and demonstrates the power of the LAr scintillation concept. A long-term stability (about 2 year) with light yield of 1800 pe/MeV was achieved.

The **Pulse Shape Discrimination** methods were developed, which allow to perform gamma / alpha / neutron selection with a strong discrimination factor for background suppression.

It was shown that the **LAr scintillator** is a powerful tool

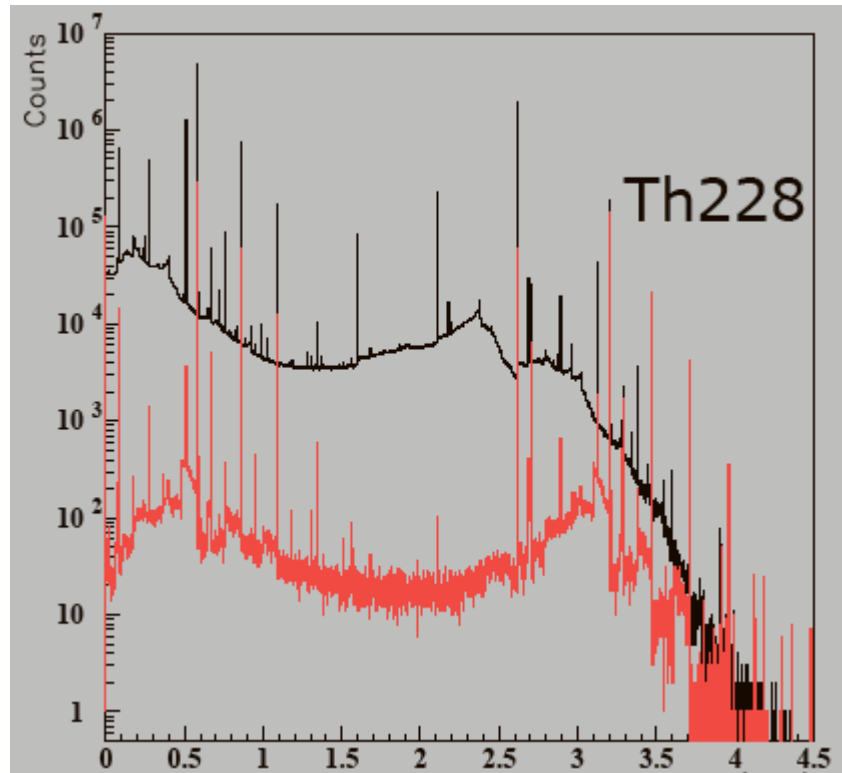

to be used in the GERDA Phase II and III as:

- 1. Gamma spectrometer** with large active volume  
(for direct measurement of gamma background inside the GERDA facility)
- 2. Large volume Neutron detector**  
(for direct measurement of neutron background and neutron – gamma delayed (anti-) coincidence inside the GERDA facility)
- 3. Radon detector / alpha-spectrometer**  
(for direct monitoring of Radon inside the GERDA facility)

## LAr scintillation veto by tagging extra energy in LAr

*P. Peiffer et al., Nucl. Phys. B. Proc. Supp. 143(2005) 511*

**Factor 300 reduction in ROI**

## The LArGe Setup with 1.3 tons of LAr

**Lock:** Can house up to 3 strings (9 detectors)

**9 PMTs:** 8" ETL9357

**VM2000 & wavelength shifter**

**Cryostat:** Inner diameter: 90 cm,  
Volume: **1000 liter**

**Shield:**

Cu	15 cm
Pb	10 cm
Steel	23 cm
PE	20 cm

The main parts of **LArGe** are installed  
in the LNGS underground facility GDL

The **liquid argon filling** was carried out **on November 1**. LAr is sub-cooled to -188 C (boiling temperature is -186 C) with a liquid nitrogen flow corresponding to 2.2 m<sup>3</sup>/hour. The filling level is stable and **no argon is lost** in this operational mode. The next steps are the start-up of the PMTs, their calibration, monitoring of the scintillation light yield and first background measurements of <sup>39</sup>Ar and of radon.

## The MAJORANA project

The planned MAJORANA experiment will consist of a few hundred detectors enriched in  $^{76}\text{Ge}$  grouped into a collection of modules constructed from electroformed copper.

All detectors will be segmented or point contact types and instrumented for pulse-shape analysis. The plan is to house about **55 kg of crystals per cryostat**, arranging cryostats in pairs such that **500 crystals of about 1.05 kg each** would comprise the **525 kg of  $^{76}\text{Ge}$**  in the total experiment.

Now the **MAJORANA** project is in the **R & D** stage.  
Initial phase: **R&D demonstrator module**: Total 60 kg (30 kg of  $^{76}\text{Ge}$  .)

# The $2\nu\beta\beta$ factory **NEMO-3**

The NEMO-3 is a combined (track gas detectors + scintillation calorimeters + magnetic field) facility capable to measure not only the total energy of  $\beta\beta$ -decay electrons but also all other parameters of this process for  $\beta\beta$ -interesting isotopes of total mass up to 10 kg

Source: 10 kg of  $\beta\beta$  isotopes  
cylindrical,  $S = 20 \text{ m}^2$ ,  $60 \text{ mg/cm}^2$

Tracking detector:  
drift wire chamber operating  
in Geiger mode (6180 cells)

Calorimeter:  
1940 plastic scintillators  
coupled to low radioactivity PMTs

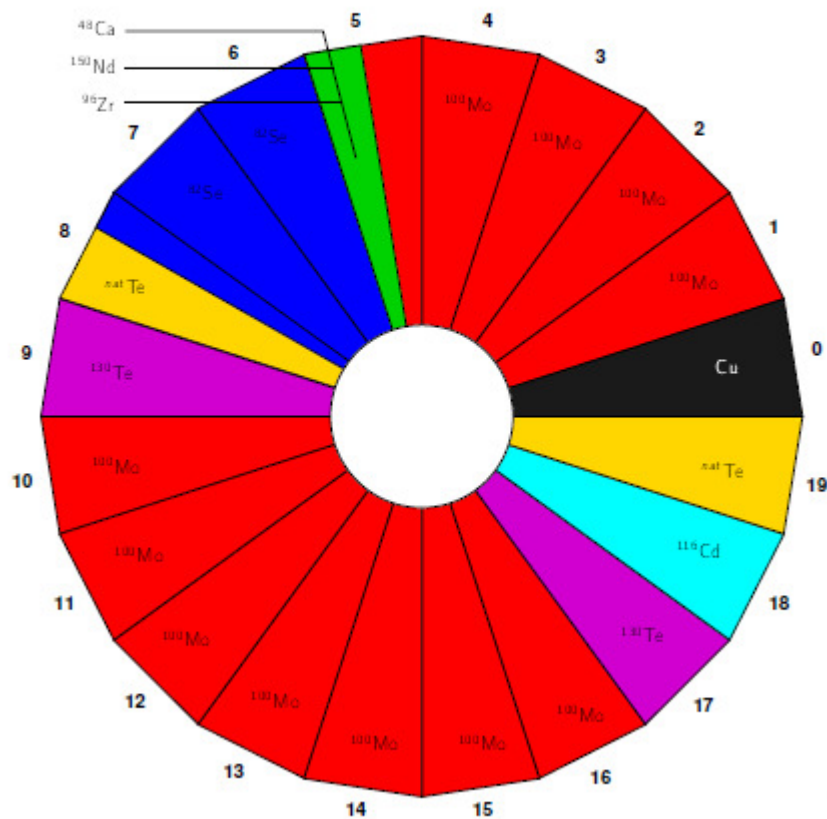

Magnetic field: 25 Gauss  
Gamma shield: Pure Iron (18 cm)  
Neutron shield: borated water  
+ Wood

## Calorimetry + Tracking

- Reconstruction of final state topology and kinematics for double beta decays, and nuclear decays from natural radioactivity:
  - ▶  $e^\pm$  individual energy (100 keV-10MeV),
  - ▶ charged particle trajectory ( $e^\pm$ ,  $\alpha$ ,  $\mu$ )
  - ▶ angular distribution, vertex, magnetic field curvature
  - ▶ time of flight,
- Background rejection through particle identification:  $e^-$ ,  $e^+$ ,  $\gamma$ ,  $\alpha$
- Source is separated from the detector: can measure several  $\beta\beta$  isotopes

## $\beta\beta$ decay isotopes

# SuperNEMO project

## Physics goals and technique

- Search for  $0\nu\beta\beta$  decay at  $T_{1/2} \simeq 10^{26}$  y  $\leadsto \langle m_\nu \rangle \simeq 50$  meV
- Extends and improves NEMO-3 technique:  
tracker+calorimeter, modular design, baseline  $\simeq 100$  kg  $^{82}\text{Se}$
- R&D phase: 2005-2009

## R&D stages

### Source:

- baseline with  $^{82}\text{Se}$  (already have 4.5 kg),
- purification techniques are available: chemical & distillation
- 40 mg/cm<sup>2</sup> foil production: ala NEMO-3 & new coating method
- 100 kg enrichment is possible by centrifugation in Russia

### Thin source foil radiopurity:

- BiPo1 0.8 m<sup>2</sup> prototype detector: measure the radiopurity of thin foils in  $^{214}\text{Bi}$  and  $^{208}\text{Tl}$   
 $\leadsto A(^{212}\text{Bi}) \simeq 1\mu\text{Bq/m}^2$  (after 1 year)
- next step: BiPo 3.5 m<sup>2</sup> detector: sensitivity  $A(^{208}\text{Tl}) < 3\mu\text{ Bq/kg}$  (after 6 monthes)

### Tracker:

- 90 cells prototype shows good tracking performances (efficiency and resolution)
- wiring robot is under development (full detector is  $\simeq 500000$  wires)

### Calorimeter:

- main goal is  $r=7\%$  FWHM @ 1 MeV (scintillator block + 8" PMT)
- accurate calibration and control quality of mass production
- $r=6.7\%$  and  $7.8\%$  have been reached resp. with **Photonis** and **Hamamatsu** high QE PMTs + 10 cm thick plastic scintillator block.
- Calorimeter design to be chosen between:
  - ▶ blocks (15000 channels @  $r=7\%$ )
  - ▶ or bars (7500 ch. @  $r=10\%$ )

## SuperNEMO demonstrator (1<sup>st</sup> module)

- Demonstrate the feasibility of a large scale detector with required performances: efficiency, energy resolution, radiopurity...
- Measure the [radon background](#)
- Finalize the detector design
- Produce competitive physics measurements:  
 $T_{1/2}^{0\nu\beta\beta} > 6.5 \cdot 10^{24} \text{ y}$   
 $\langle m_\nu \rangle < 210 - 570 \text{ meV}$   
with 7 kg of <sup>82</sup>Se after 2 y of data taking
- Schedule:
  - ▶ construction: 2010-2011 (+BiPo 3.5 m<sup>2</sup>)
  - ▶ running: 2012-2013
- Location: possibly @ LSM (in place of NEMO 3)

## SuperNEMO full detector

- Baseline:  $\simeq 20$  modules with 5 kg of  $^{82}\text{Se}$
- Other candidate isotopes:  $^{48}\text{Ca}$  and  $^{150}\text{Nd}$
- Expected sensitivity with 500 kg.y of  $^{82}\text{Se}$  (preliminary):  
$$T_{1/2}^{0\nu\beta\beta} > 1 \cdot 10^{26} \text{ y} \rightsquigarrow \langle m_\nu \rangle < 53 - 145 \text{ meV}$$
- Schedule:
  - ▶ construction: 2012+
  - ▶ running: 2013+
- Location: new 60000 m<sup>3</sup> extension at LSM (2012)

## CONCLUSION

New generation of the of the  $0\nu\beta\beta$  experiments

has a good chance  
to penetrate deeper

in understanding  
of the neutrino properties

$\nu$
