Introduction — Motivation

- The aim of future neutrino experiments is the precision measurement of the oscillation parameters such as θ_{13} and δ_{CP}
 - Osc. probabilities will be measured with $\mathcal{O}(1-0.1)\%$ or higher accuracy.
 - We have a good chance to observe not only the standard oscillation phenomena but also the sub-leading effects induced by non-standard interactions (NSIs).

Introduction — Motivation

- The aim of future neutrino experiments is the precision measurement of the oscillation parameters such as θ_{13} and δ_{CP}
 - Osc. probabilities will be measured with $\mathcal{O}(1-0.1)\%$ or higher accuracy.
 - We have a good chance to observe not only the standard oscillation phenomena but also the sub-leading effects induced by non-standard interactions (NSIs).
- NSIs — Flavour violating interactions with neutrinos such as $\nu_{\alpha}f \rightarrow \nu_{\beta}f$, $\ell_{\alpha}^{-} \rightarrow \nu_{\beta}e^{-}\bar{\nu}_{e}\dots$

Introduction — Motivation

- The aim of future neutrino experiments is the precision measurement of the oscillation parameters such as θ_{13} and δ_{CP}

- Osc. probabilities will be measured with $\mathcal{O}(1-0.1)\%$ or higher accuracy.
- We have a good chance to observe not only the standard oscillation phenomena but also the sub-leading effects induced by non-standard interactions (NSIs).

- NSIs — Flavour violating interactions with neutrinos such as $\nu_\alpha f \rightarrow \nu_\beta f, \ell_\alpha^- \rightarrow \nu_\beta e^- \bar{\nu}_e \dots$

- It can be written as eff. 4-Fermi int. as
$$-\mathcal{L}_{\text{NSI}} = 2\sqrt{2}G_F\epsilon_{\beta\alpha}^m (\bar{\nu}_\beta \gamma^\rho P_L \nu_\alpha) (\bar{f} \gamma_\rho P_{L/R} f)$$

— We study the discovery reach of the NSIs in the osc. exp.

Introduction — Standard oscillation

- A long baseline exp. can be described diagrammatically as

$$\mathcal{A}(\nu_\mu N \rightarrow \mu^- X) \langle \nu_\mu | e^{-iHL} | \nu_e \rangle \mathcal{A}(\mu^+ \rightarrow e^+ \bar{\nu}_\mu \nu_e)$$

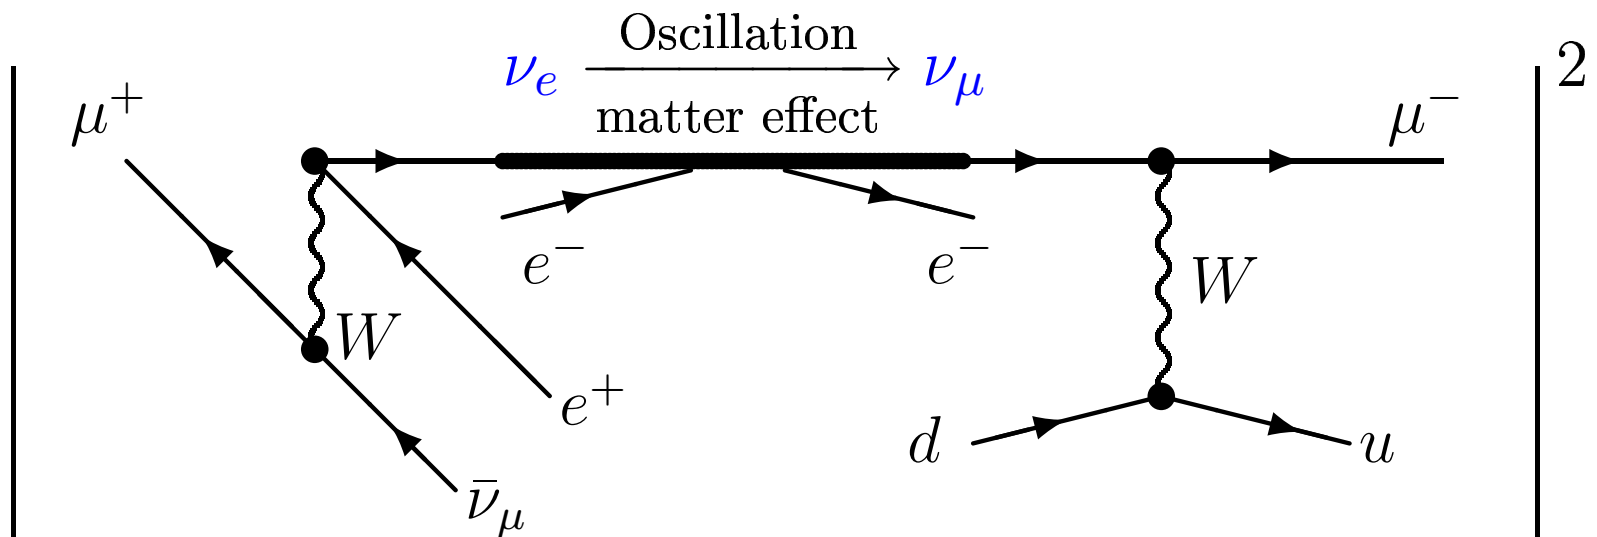

Introduction — Standard oscillation

- A long baseline exp. can be described diagrammatically as

$$\left| \mathcal{A}(\nu_\mu N \rightarrow \mu^- X) \langle \nu_\mu | e^{-iHL} | \nu_e \rangle \mathcal{A}(\mu^+ \rightarrow e^+ \bar{\nu}_\mu \nu_e) \right|^2$$

||

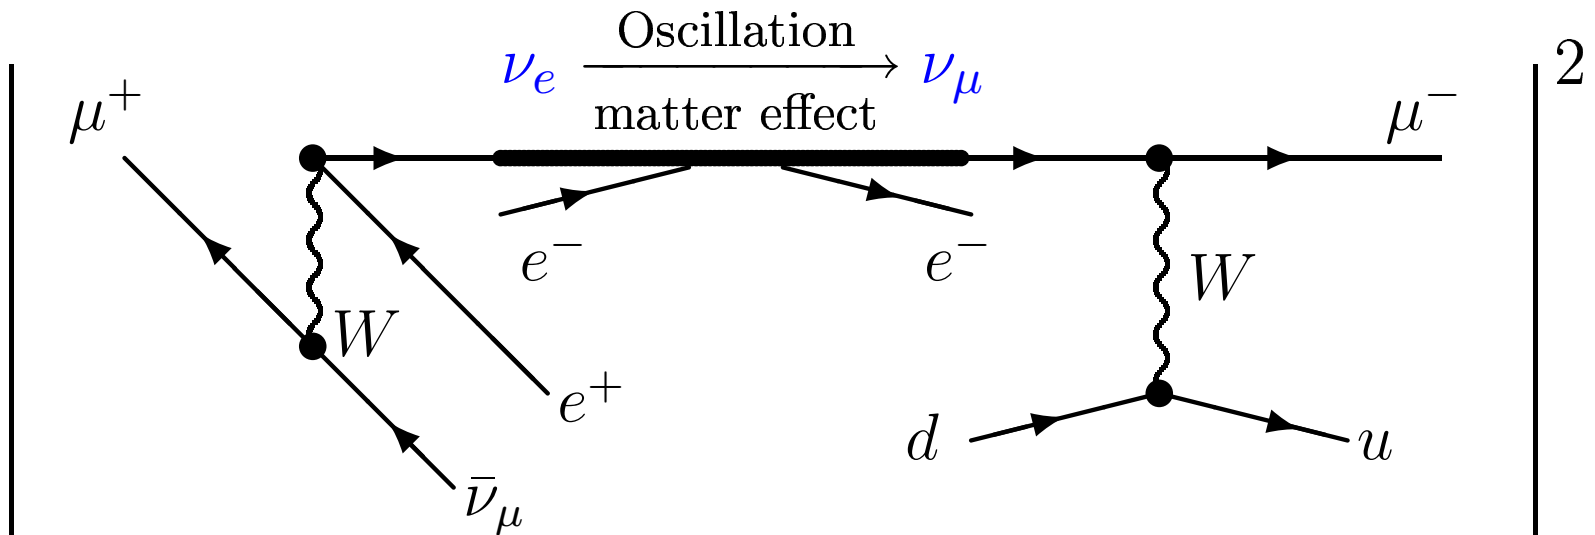

Introduction — Standard oscillation

- A long baseline exp. can be described diagrammatically as

$$\sigma(\nu_\mu N \rightarrow \mu^- X) \times P_{\nu_e \rightarrow \nu_\mu} \times \Gamma(\mu^+ \rightarrow e^+ \bar{\nu}_\mu \nu_e)$$

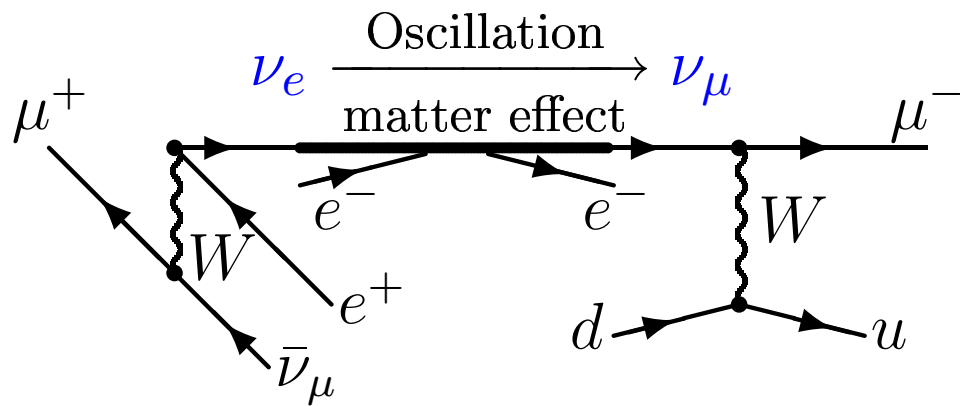

||

Introduction — Oscillation enhanced search for NSIs

- ν osci. = Flavour changing process

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{osc}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

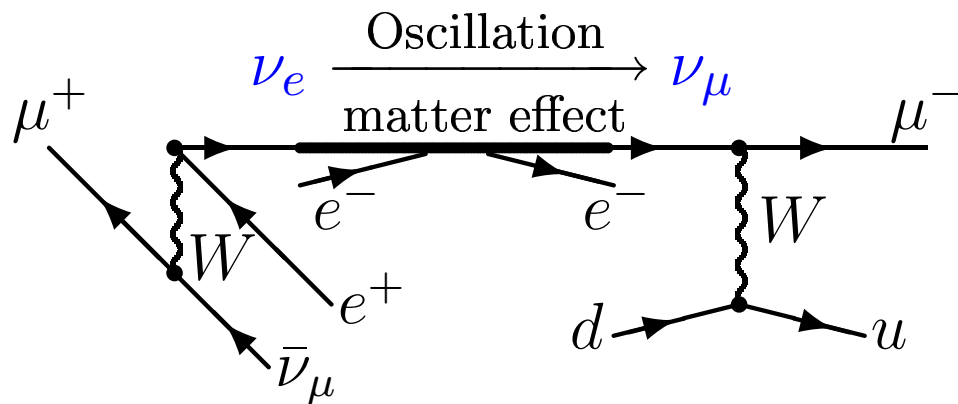

Introduction — Oscillation enhanced search for NSIs

- ν osci. = Flavour changing process

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{osc}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

- The process with NSI is similar

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{NSI}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

Introduction — Oscillation enhanced search for NSIs

- ν osci. = Flavour changing process

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{osc}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

- The process with NSI is similar

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{NSI}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

— They interfere with each other.

- The signals of NSI appear in the osc. probability at $\mathcal{O}(\epsilon_{e\mu}^m)$.
— This is quite different from the charged lepton LFV process.
e.g., $\text{Br}(\mu \rightarrow 3e)$ is proportional to $|\epsilon_{e\mu}^m|^2$.

Introduction — Oscillation enhanced search for NSIs

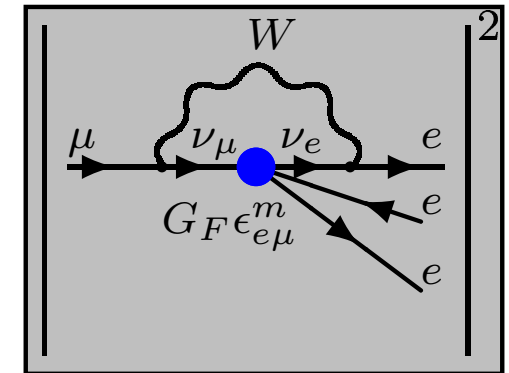

- ν osci. = Flavour changing process

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{osc}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

- The process with NSI is similar

$$\ell_{\alpha}^{-} \xrightarrow{\text{CC}} \nu_{\alpha} \xrightarrow{\text{NSI}} \nu_{\beta} \xrightarrow{\text{CC}} \ell_{\beta}^{-}$$

— They interfere with each other.

$$|\epsilon_{e\mu}^m| < 5 \times 10^{-4} \text{ (90\%CL)}$$

- The signals of NSI appear in the osc. probability at $\mathcal{O}(\epsilon_{e\mu}^m)$.
 — This is quite different from the charged lepton LFV process.
 e.g., $\text{Br}(\mu \rightarrow 3e)$ is proportional to $|\epsilon_{e\mu}^m|^2$.

Introduction — NSIs in matter

- NSIs in matter can be described by extra potential terms
— We parametrize them as

$$H_{\beta\alpha} = \frac{1}{2E_\nu} \left\{ U \begin{pmatrix} 0 & & \\ & \Delta m_{21}^2 & \\ & & \Delta m_{31}^2 \end{pmatrix} U^\dagger + \begin{pmatrix} a_{\text{CC}} & & \\ & 0 & \\ & & 0 \end{pmatrix} + (V_{\text{NSI}})_{\beta\alpha} \right\},$$

$$(V_{\text{NSI}})_{\beta\alpha} = a_{\text{CC}} \begin{pmatrix} \epsilon_{ee}^m & \epsilon_{e\mu}^m & \epsilon_{e\tau}^m \\ (\epsilon_{e\mu}^m)^* & \epsilon_{\mu\mu}^m & \epsilon_{\mu\tau}^m \\ (\epsilon_{e\tau}^m)^* & (\epsilon_{\mu\tau}^m)^* & \epsilon_{\tau\tau}^m \end{pmatrix}$$

- In general, each off-diagonal (flavour violating) element has a complex phase.

Discovery reach for NSIs in neutrino factory

- Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory
 - how small $|\epsilon_{e\mu}^m|$ can be found in the neutrino factory.
- We introduce a NSI as the complex parameter
 - There is no reason to consider it is a real parameter.
 - The discovery reach strongly depends on the phase.
- We turn off all NSIs other than the NSI which we study.
- Modified GLoBES software is used.
- The following values are adopted as the true value of the standard oscillation parameters

$$\sin^2 2\theta_{12}^{\text{true}} = 0.83, \quad \sin^2 2\theta_{13}^{\text{true}} = 0.01, \quad \sin^2 2\theta_{23}^{\text{true}} = 1.0,$$
$$(\Delta m_{21}^2)^{\text{true}} = 8.2 \times 10^{-5} \text{ [eV}^2\text{]}, \quad (\Delta m_{31}^2)^{\text{true}} = 2.5 \times 10^{-3} \text{ [eV}^2\text{]}.$$

Discovery reach for NSIs in neutrino factory

- Discovery reach for $|(\epsilon_{e\mu}^m)^{\text{true}}|$ is determined by^a

$$\chi^2 \equiv \min_{\lambda} \sum_i^{\text{bin}} |N_i(\lambda^{\text{true}}, (\epsilon_{e\mu}^m)^{\text{true}}) - N_i(\lambda, \epsilon_{e\mu}^m = 0)|^2 / V_i,$$

where $\lambda \in \{\theta_{12}, \theta_{13}, \theta_{23}, \delta_{\text{CP}}, \Delta m_{21}^2, \Delta m_{31}^2, a_{\text{CC}}\}$.

- If $\chi^2 > \chi_{3\sigma}^2$, the effect induced by the NSI with the value of $|(\epsilon_{e\mu}^m)^{\text{true}}|$ will be discovered at the 3σ level.

- Undetermined parameters: $\delta_{\text{CP}}^{\text{true}}$ and $\arg[(\epsilon_{e\mu}^m)^{\text{true}}]$
 - We scan the value of χ^2 on the $\delta_{\text{CP}}^{\text{true}}$ - $\arg[(\epsilon_{e\mu}^m)^{\text{true}}]$ plane for the fixed $|(\epsilon_{e\mu}^m)^{\text{true}}|$.

^a In the numerical calculation, we use the χ^2 function for the Poisson distribution.

Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory

- In the case $|(\epsilon_{e\mu}^m)^{\text{true}}| = 5 \times 10^{-4}$,

- $|\epsilon_{e\mu}^m|$ is too small

↓
 χ^2 cannot exceed 3σ on the whole parameter plane. (Under the sea)

↓
The deviation from the standard oscillation is not significant

↓
No chance to discover!

Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory

- In the case $|(\epsilon_{e\mu}^m)^{\text{true}}| = 6 \times 10^{-4}$,

- $|\epsilon_{e\mu}^m|$ becomes larger

In some regions χ^2 exceeds 3σ
(Islands appear)

The deviation from the
standard oscillation is
significant at 3σ

We have a chance to discover
NSI effect depending on the
phases

Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory

- In the case $|(\epsilon_{e\mu}^m)^{\text{true}}| = 1 \times 10^{-3}$,

- $|\epsilon_{e\mu}^m|$ becomes larger

↓
In some regions χ^2 exceeds 3σ
(Islands appear)

↓
The deviation from the
standard oscillation is
significant at 3σ

↓
We have a chance to discover
NSI effect depending on the
phases

Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory

- In the case $|(\epsilon_{e\mu}^m)^{\text{true}}| = 2 \times 10^{-3}$,

- $|\epsilon_{e\mu}^m|$ becomes larger

In some regions χ^2 exceeds 3σ
(Islands appear)

The deviation from the
standard oscillation is
significant at 3σ

We have a chance to discover
NSI effect depending on the
phases

Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory

- In the case $|(\epsilon_{e\mu}^m)^{\text{true}}| = 4 \times 10^{-3}$,

- $|\epsilon_{e\mu}^m|$ becomes larger

↓
In some regions χ^2 exceeds 3σ
(Islands appear)

↓
The deviation from the
standard oscillation is
significant at 3σ

↓
We have a chance to discover
NSI effect depending on the
phases

Discovery reach for $\epsilon_{e\mu}^m$ in neutrino factory

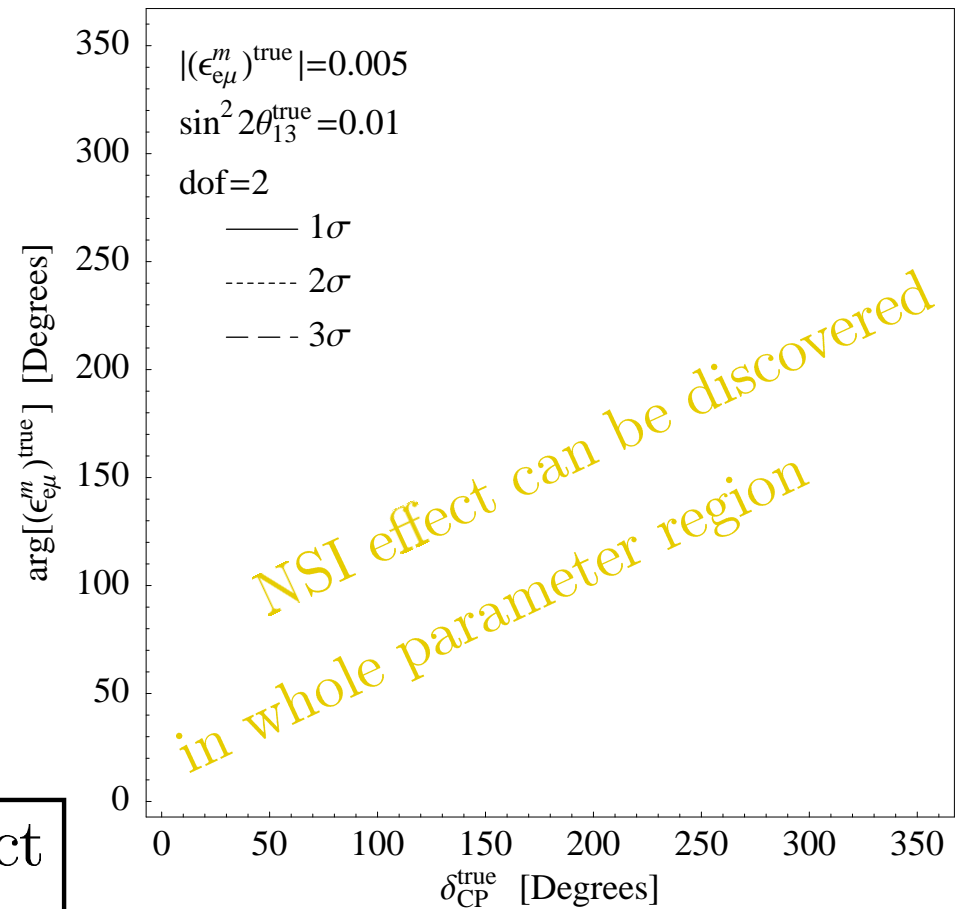

- In the case $|(\epsilon_{e\mu}^m)^{\text{true}}| = 5 \times 10^{-3}$,

- $|\epsilon_{e\mu}^m|$ is large enough

↓
 χ^2 exceeds 3σ on the whole parameter plane
(The sea disappears)

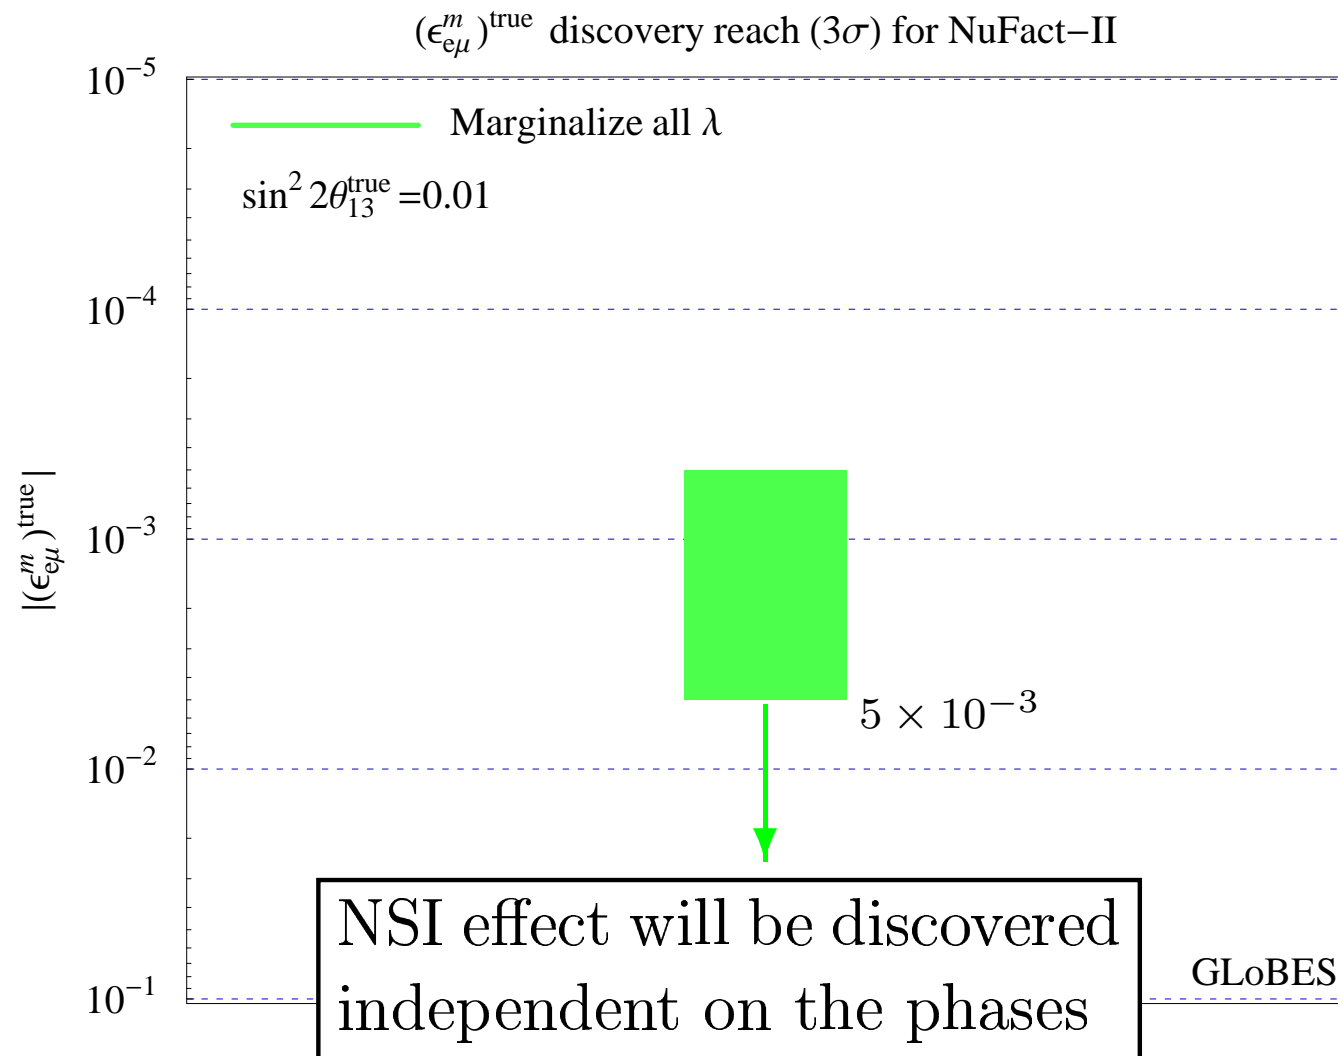

↓
The deviation from the standard oscillation is significant at 3σ

↓
We can observe the NSI effect with any values of phases.

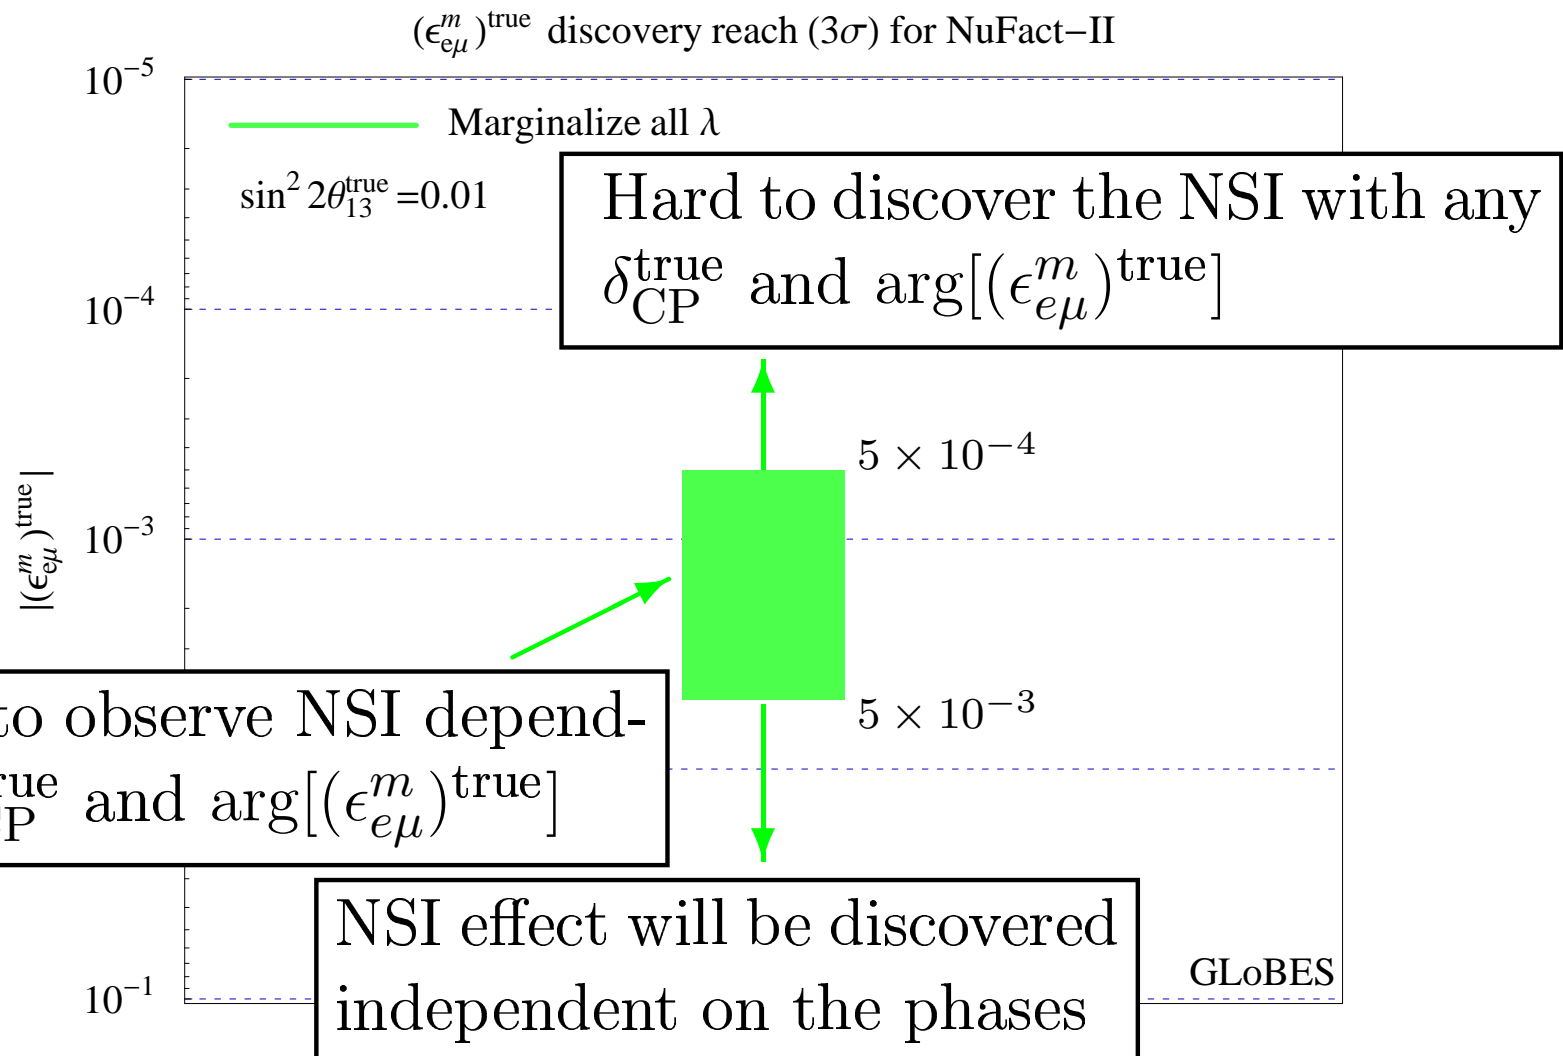

Discovery reach for NSIs in neutrino factory

- Summary plot for the discovery reach of $\epsilon_{e\mu}^m$

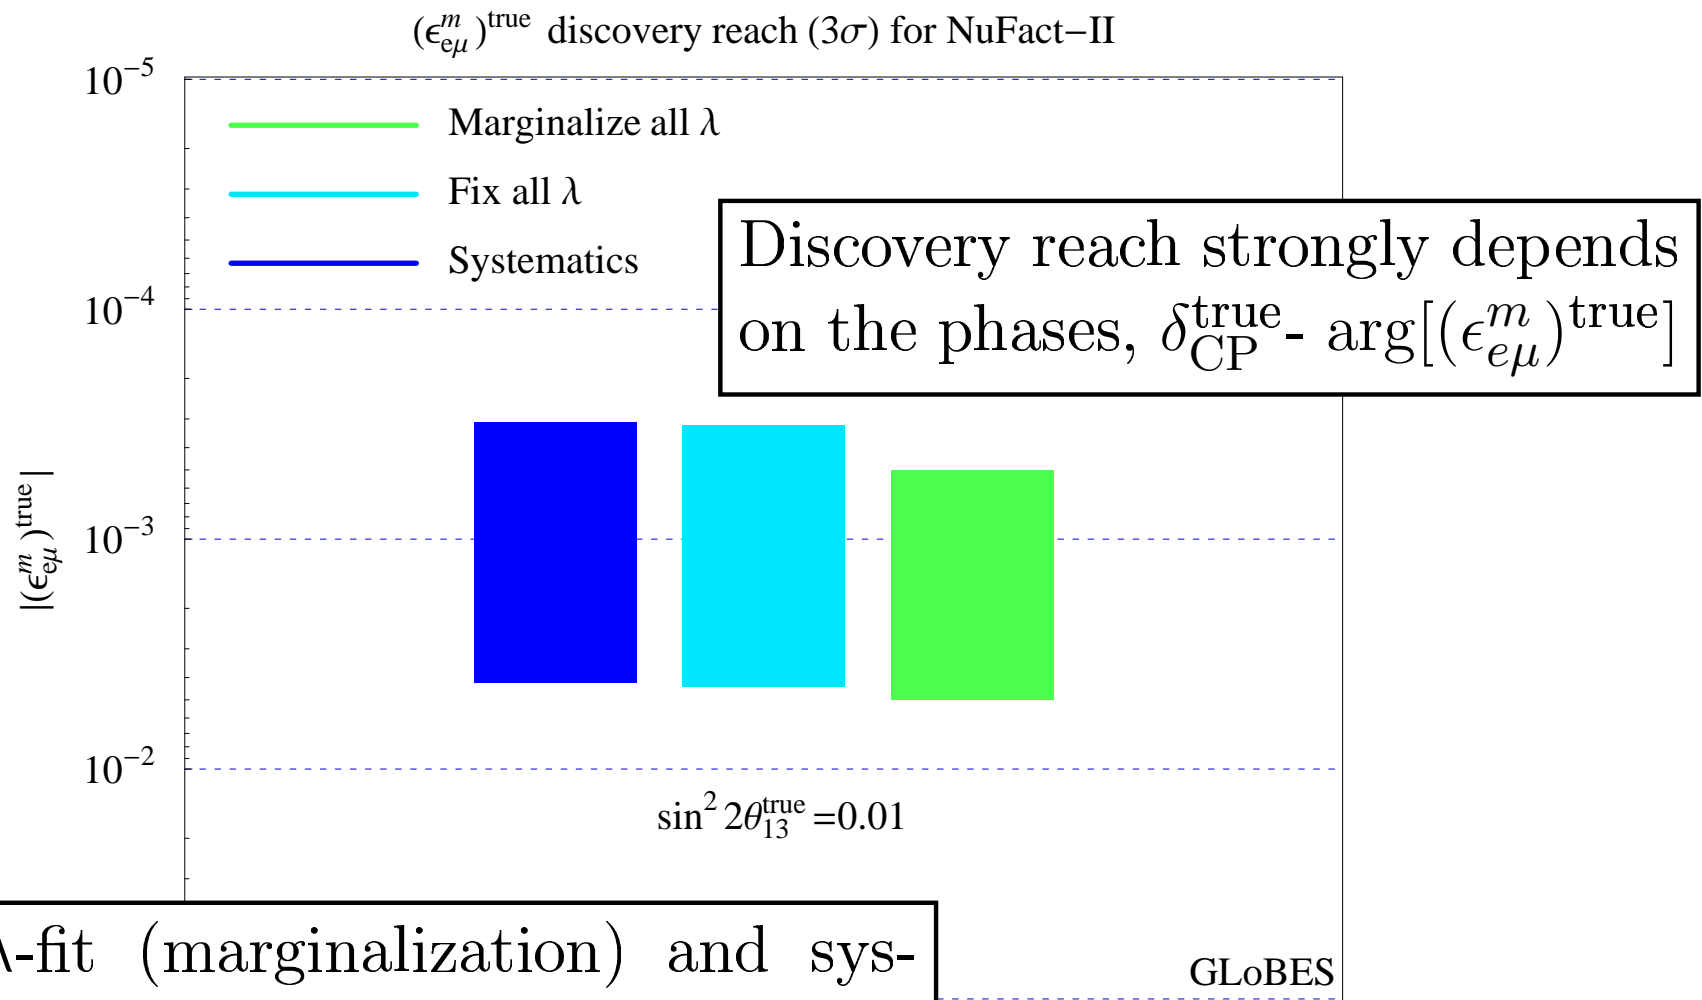

Discovery reach for NSIs in neutrino factory

Discovery reach for NSIs in neutrino factory

- Similar plot for the discovery reach of $\epsilon_{e\tau}^m$

Summary

Summary

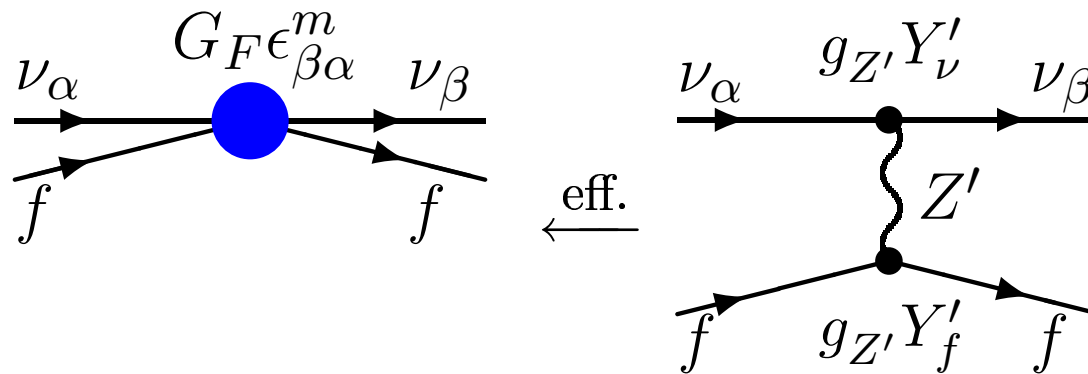

- We have studied the discovery reach for the NSIs in a neutrino factory.
- The undetermined parameters $\delta_{\text{CP}}^{\text{true}}$ and $\arg[\epsilon^{\text{true}}]$ are scanned.

For $\epsilon_{e\mu}^m$, when $\sin^2 2\theta_{13}^{\text{true}} = 0.01$

- With $|\epsilon_{e\mu}^m| \geq 5 \times 10^{-4}$,
we have a chance to discover the effect at the 3σ level,
depending on the phases.
 - If $|\epsilon_{e\mu}^m| \geq 5 \times 10^{-3}$,
it can be found in the ν factory regardless of the phases.
- Current bound from $\mu \rightarrow 3e$ is 5×10^{-4} at the 90% CL.
— Comparable, depending on the phases

Summary

- The discovery reach for $\epsilon_{e\tau}^m$ and $\epsilon_{e\mu}^s$ has also studied.
 - $|\epsilon_{e\mu}^s| \sim \mathcal{O}(10^{-3,-4})$, $|\epsilon_{e\tau}^m| \sim \mathcal{O}(10^{-1,-2})$.
- The effective four-Fermi NSIs with $\epsilon \sim \mathcal{O}(10^{-2})$ may mean the TeV scale physics, i.e.,

- If $g_{Z'}$ is the same as g_Z , $\epsilon_{\beta\alpha}^m = m_Z^2/m_{Z'}^2$.

-
- NSIs are not good signals for MSSM
 - They are strongly suppressed
 - NSIs may be the signals for something else than MSSM

Discussion: NSIs in models

References : T. O and J. Sato, Phys. Rev. **D71** (2005) 096004.

NSIs in models

- We dealt with NSIs as effective 4-Fermi interactions so far.
- Current experimental bounds coming from the LFV process

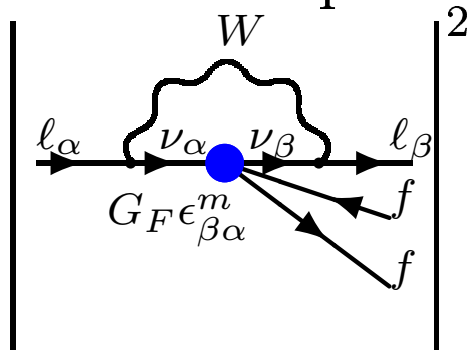

$$\overline{\overline{\epsilon_{e\mu}^m (f = e) \quad 5 \times 10^{-4} \text{ (90\% CL)}}}}$$

$$\overline{\overline{\epsilon_{e\tau}^m (f = e) \quad 2.9 \text{ (90\% CL)}}}}$$

Comparable with discovery reach in ν fact.

NSIs in models

- We dealt with NSIs as effective 4-Fermi interactions so far.
- Current experimental bounds coming from the LFV process

$$\overline{\overline{\epsilon_{e\mu}^m (f = e) \quad 5 \times 10^{-4} \text{ (90\% CL)}}}}$$

$$\overline{\overline{\epsilon_{e\tau}^m (f = e) \quad 2.9 \text{ (90\% CL)}}}}$$

Comparable with discovery reach in ν fact.

- These eff. int.s can be interpreted as *extra weak interactions*

- If $g_{Z'}$ are the same as those of weak interaction, $\epsilon_{\beta\alpha}^m = m_Z^2 / m_{Z'}^2$,
- $\epsilon_{\alpha\beta}^m \sim \mathcal{O}(10^{-2})$ means *access to the TeV scale physics*

NSIs in models — MSSM with ν_R

- In the MSSM, NSIs and $\ell_\beta \rightarrow \ell_\alpha \gamma$ are provided by similar one-loop diagrams with slepton mixings — they are correlated.

- Large slepton mixings are expected to be induced by the RGE effect associated with the neutrino Yukawa couplings.
- $\epsilon_{e\mu}^{s,m}$ is strongly suppressed, at least $\sqrt{\text{Br}(\mu \rightarrow e\gamma)} = \mathcal{O}(10^{-5})$
- How about $\epsilon_{e\tau}^m, \epsilon_{\mu\tau}^m$?

NSIs in models — MSSM with ν_R

and box diagrams ...

NSIs in models — MSSM with ν_R

- Correlation between the NSI coupling $\epsilon_{\mu\tau}^m$ and LFV process $\tau \rightarrow \mu\gamma$.
- With some different Y_ν s, we scan the m_0 - $M_{1/2}$ space with $a_0 = 0$, $\tan\beta = 3, 10$, and $\mu > 0$.
- The parameter $\epsilon_{\mu\tau}^m$ is constrained at $\mathcal{O}(10^{-6})$ by the current bound of $\tau \rightarrow \mu\gamma$.
- It is smaller than the naive estimation because of cancellation among diagrams.
