Lecture:

Standard Model of Particle Physics

Heidelberg SS 2012

Experimental Tests of QED Part 2

Overview

PART I

- Cross Sections and QED tests
- Accelerator Facilities + Experimental Results and Tests

PART II

- Tests of QED in Particle Decays
- QED Radiative Effects (Bremsstrahlung, Higher Order Processes)

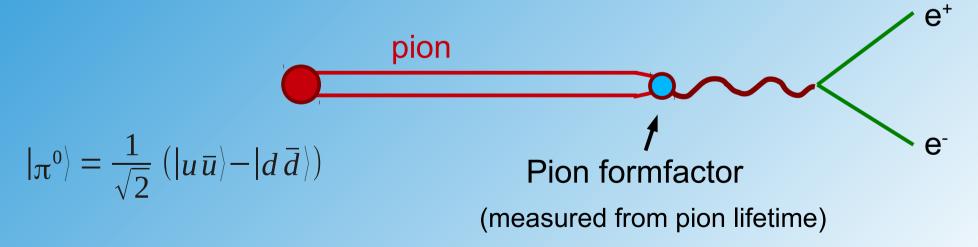

Electromagnetic Decay of Pion

- Pion is the lightest hadron (meson)
- consists of u and d quarks (isospin triplet)
- No strong or weak decay possible

Can the electromagnetic decay of the pion be described by QED?

Complication: quarks are involve large QCD corrections!

Solution: introduce pion form factor

Test Pion Branching Ratios

• dominant decay: $B(\pi^0 \rightarrow \gamma \gamma) = 98.823 \%$

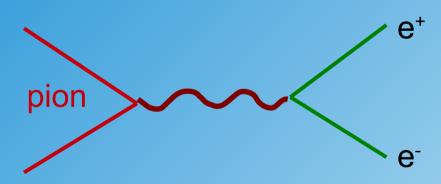

• radiative decay: $B(\pi^0 \rightarrow e^+e^-\gamma) = 1.174 \%$

• 2-prong decay: $B(\pi^0 \to e^+e^-) = 6.46 \times 10^{-8}$

Can QED describe this surprisingly small branching ratio?

Vector Currents:

$$j_{elm}^{\mu} = \overline{v}(x) \gamma^{\mu} u(x)$$
 per photon/fermion vertex

- Vector currents conserve helicity.
- Resulting spin should be $J(\pi^0)=1$
- But pion is a Pseudo-scalar $J(\pi^0)=0$
 - → contradiction → helicity suppression

Polarisation of helicity state is given by fermion velocity:

$$\langle \lambda \rangle = \pm \beta$$
 for right/left chiralities

Resulting suppression factor:

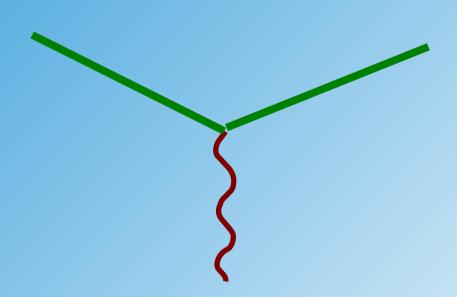

$$\frac{1}{16}(1-\beta_q^2)(1-\beta_e^2) = \frac{1}{16\gamma_q^2\gamma_q^2} = \frac{m_q^2m_e^2}{m_\pi^4}$$

no scalar couplings!

 $\sim 3 \cdot 10^{-8}$

QED Radiative Effects

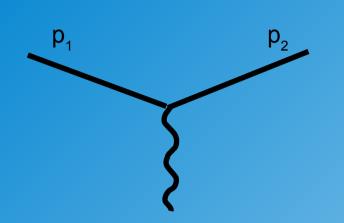

- Bremsstrahlung
- Higher Order Processes

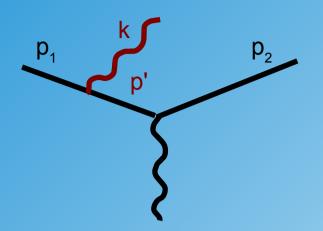

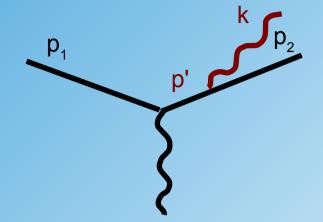

Experimentally very important:

- can be exploited for measurements (luminosity, radiative returns)
- but can also disturb measurements!

QED First Order Corrections

initial state radiation (ISR)

final state radiation (FSR)

Fermion propagator:

$$\frac{1}{p'^2 - m^2} = \frac{1}{(p_1 - k)^2 - m^2} \qquad \frac{1}{p'^2 - m^2} = \frac{1}{(p_2 + k)^2 - m^2}$$

$$\frac{1}{p'^2 - m^2} = \frac{1}{(p_2 + k)^2 - m^2}$$

ISR:

$$\frac{1}{(p_1-k)^2-m^2} = \frac{1}{p_1^2+k^2-2\,p_1k-m^2} = \frac{1}{-2\,p_1k} \approx \frac{1}{-2\,E_eE_\gamma(1-\cos\theta)} \qquad \text{(if mass small)}$$

Singularities:

- photon emission under zero degrees $\theta \rightarrow 0$
- soft photon

$$E_{\gamma} \rightarrow 0$$

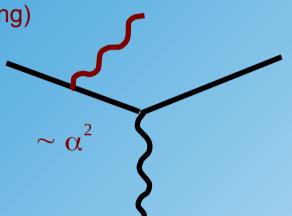

FSR: similar

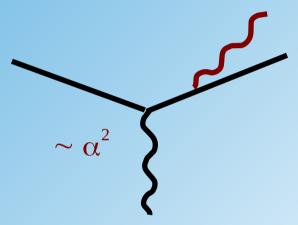

ISR + FSR: interference term shows no singularity (wide angle scattering)

QED First Order Corrections

- Singularities are not allowed in (renormalisable) gauge theories and have to cancel
- Singularity from "soft" and collinear Bremsstrahlung cancel with virtual vertex corrections in QED

"real corrections" (Bremsstrahlung)

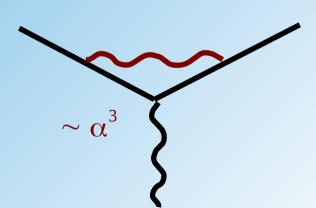

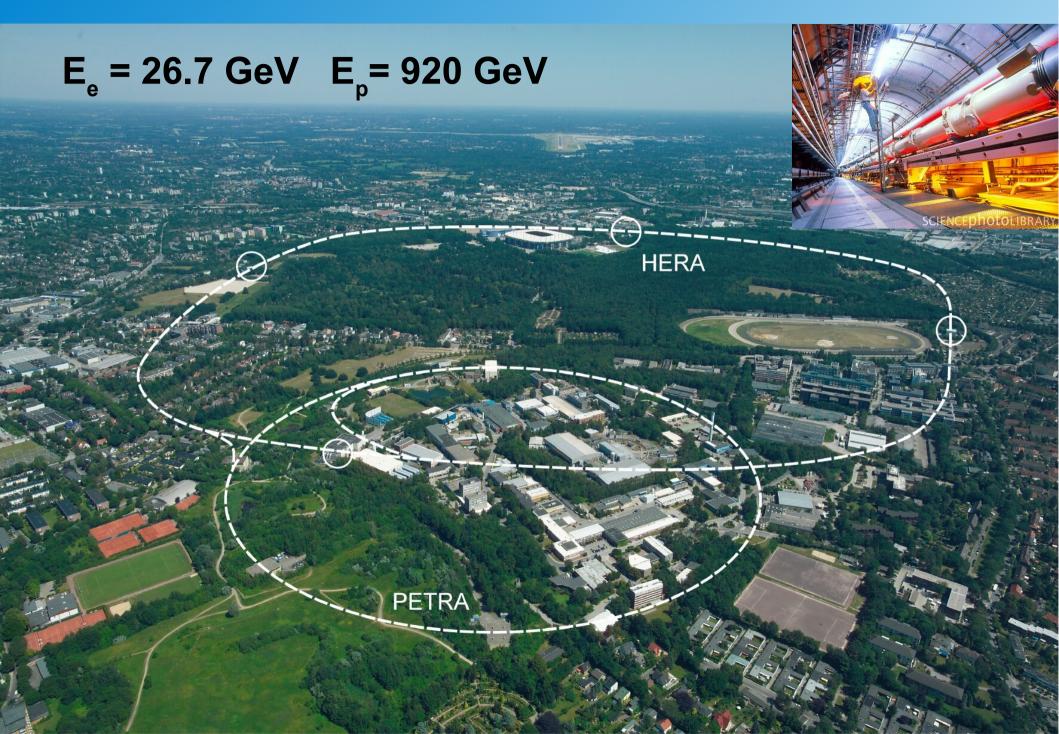

virtual correction:

interference of LO diagram and vertex correction $\sim \alpha^2$ compensates singularities from Bremsstrahlung

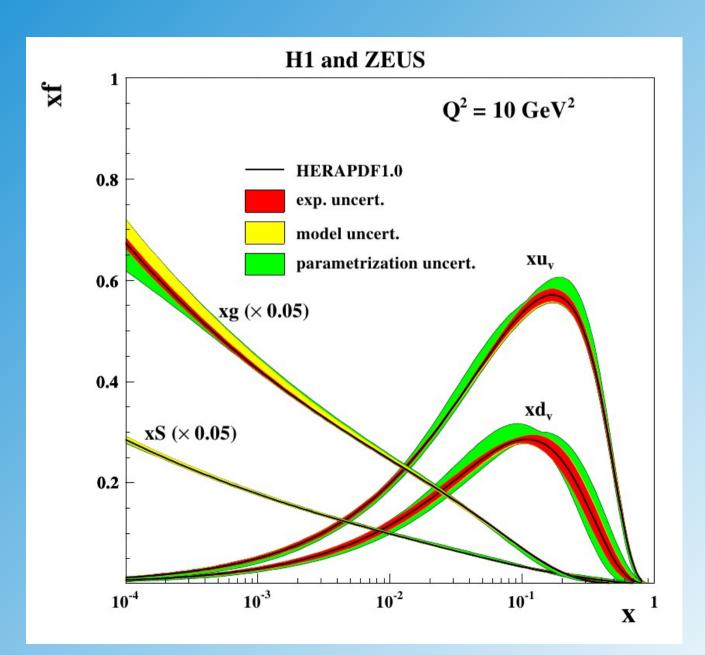

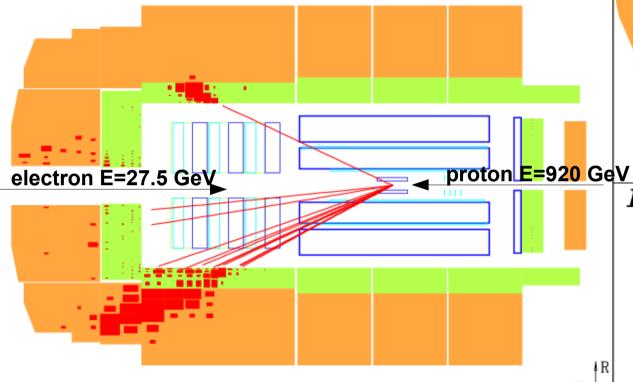

Electron-Proton Collider HERA

Proton Parton Densities

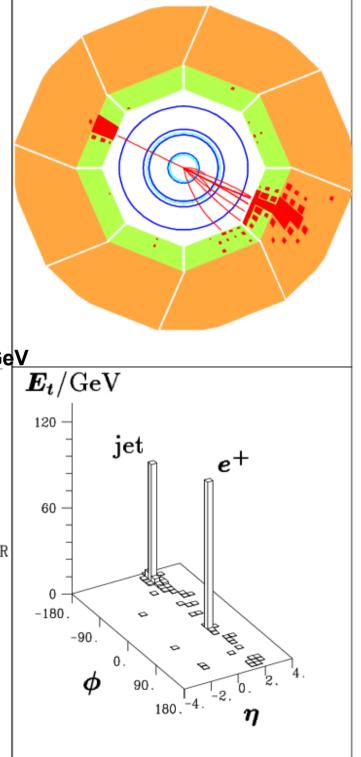

$$Q^2=25030~{
m GeV^2},~~y=0.56,~~M=211~{
m GeV}$$

 $ep \rightarrow e X$ (neutral current)

Kinematics Scattering Process

The virtuality of the exchanged photon is given by:

$$Q^2 = -q^2 = -(p-p')^2$$

$$\propto \frac{1}{\sin^4 \theta/2}$$

electron

Energy transfer (in Proton-rest frame):

$$\nu = E_{Elektron} - E_{Elektron}'$$

Energy of photon-proton system (hadronic final state):

$$W = m_p + \nu$$

proton

Lorentz Invariant Kinematics of Deep Inelastic Scattering Process

The virtuality of the exchanged photon is given by:

$$Q^2 = -q^2 = -(p-p')^2$$

$$\propto \frac{1}{\sin^4 \theta/2}$$

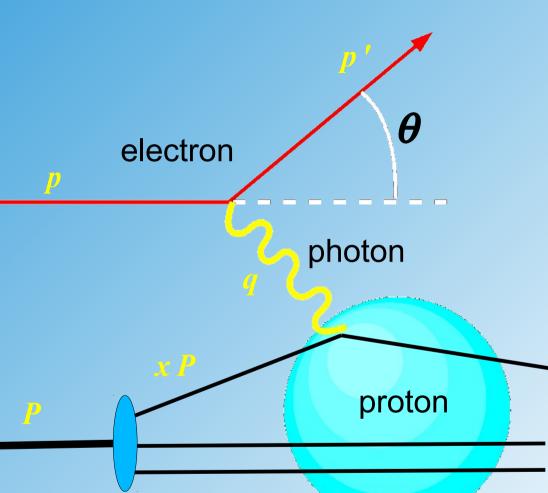

Relative energy loss (inelasticity):

$$y = \frac{v}{E_{Elektron}} = \frac{qP}{pP}$$

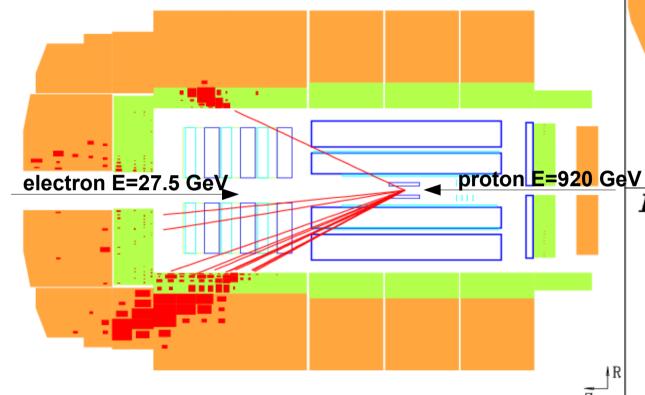

relative fraction of parton momentum:

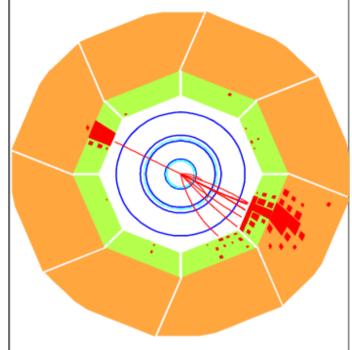

$$x = \frac{q^2}{2 q P} = \frac{Q^2}{s v}$$

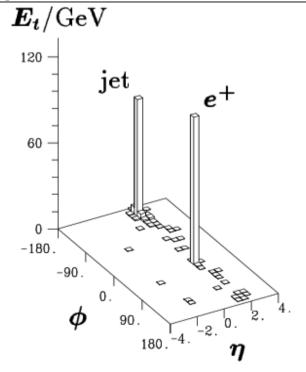

with cms energy: s = 2 p P

$$Q^2=25030~{
m GeV^2},~~y=0.56,~~M=211~{
m GeV}$$

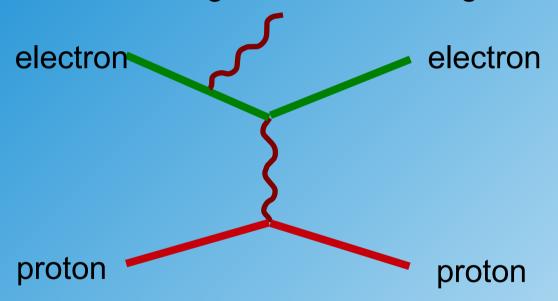

Determination of Luminosity?

Reference Process

Need process with large cross section

- Bethe Heitler Process: $e p \rightarrow ep \gamma$
- Bremsstrahlung-Process with large cross section (~ 1 barn)!

Note,

- the proton stays intact (elastic)!
- the cross section can only be given for a minimum photon energy! (infrared singularity)

Radiative Effects in Electon-**Proton Scattering**

Bremsstrahlung proportional to

$$\frac{1}{(p-k)^2-m^2}$$

Bremsstrahlung effects are large for particles with low mass

Electron mass: m_e = 0.511 MeV

Proton mass: m_n = 938 GeV

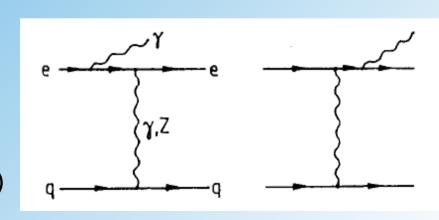

heavy radiation!

Radiation is large if

- 1. photon is soft
- 2. photon is emitted collinear

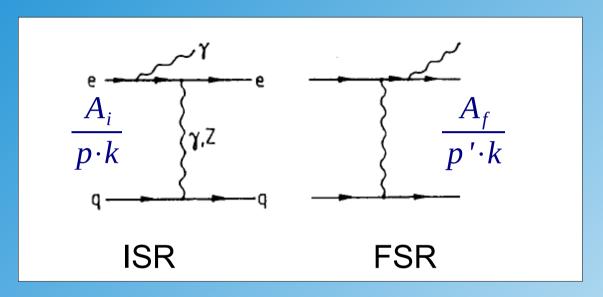

Photons can be emitted from

- 1. incoming electron (initial state radiation, ISR)
- 2. outgoing electron (final state radiation, FSR)

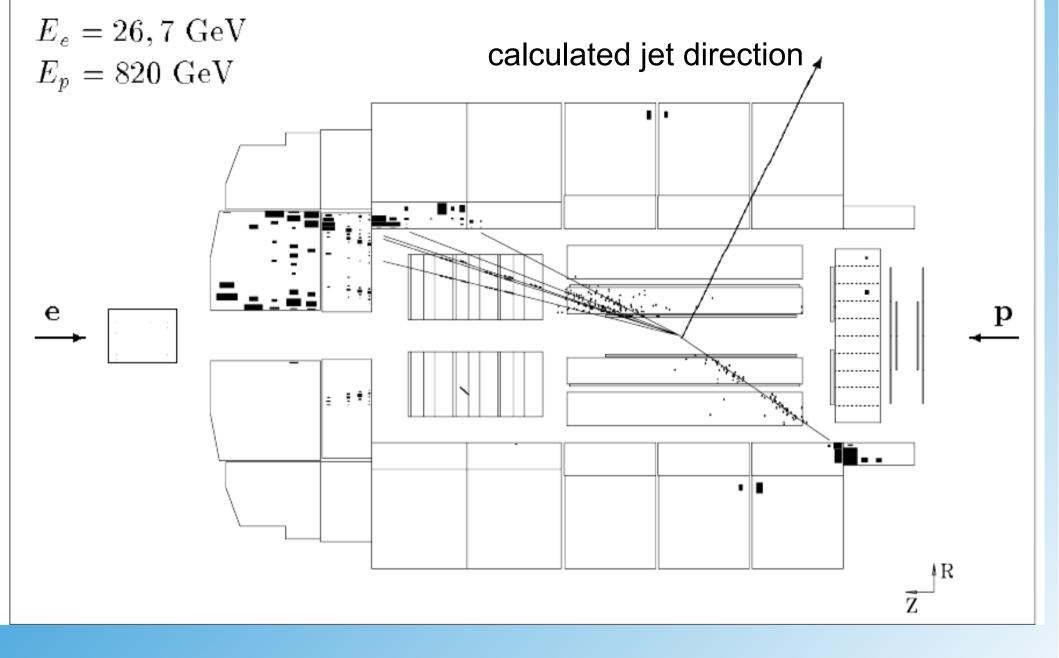

Radiative Poles

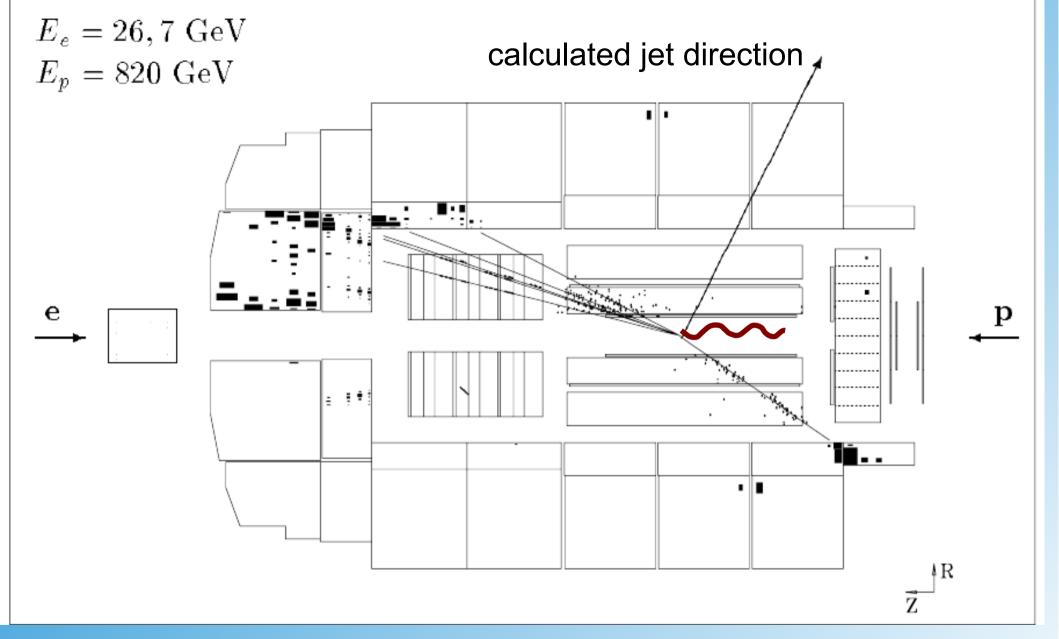

Neglecting the small electron mass, the poles become:

Note ISR reduces the available center of mass energy s^{1/2}

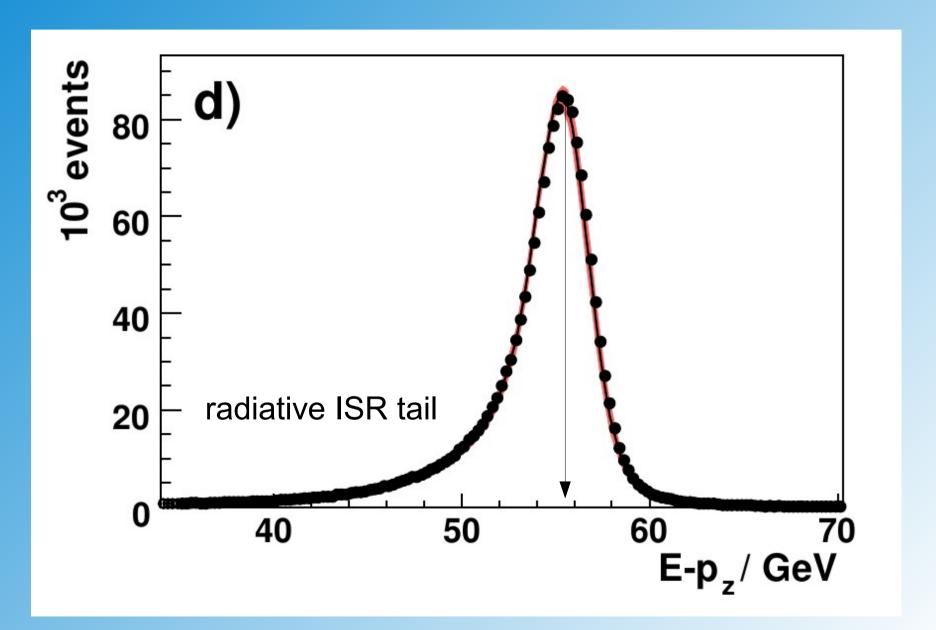

Initial State Radiation?

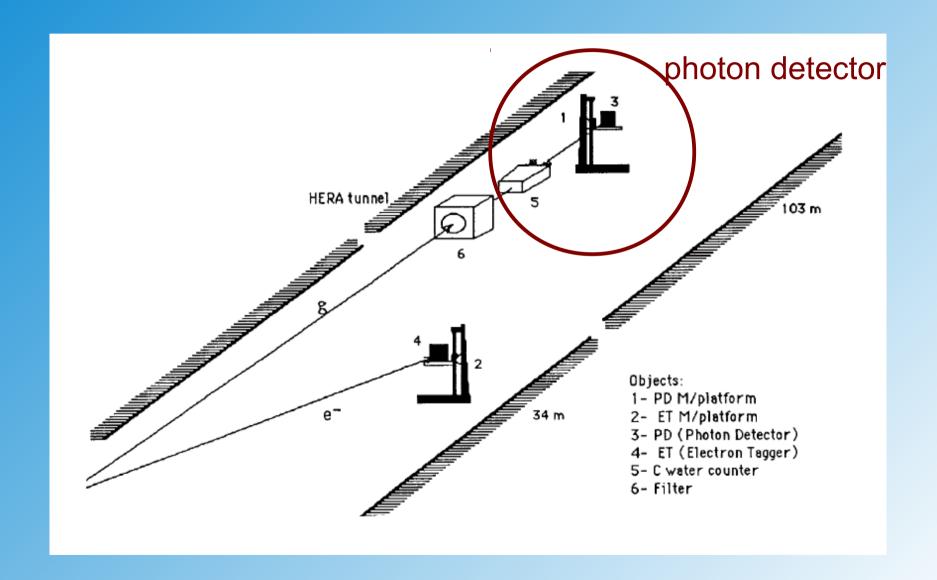

Energy E conserved and momentum p conserved $E-p_z$ conserved

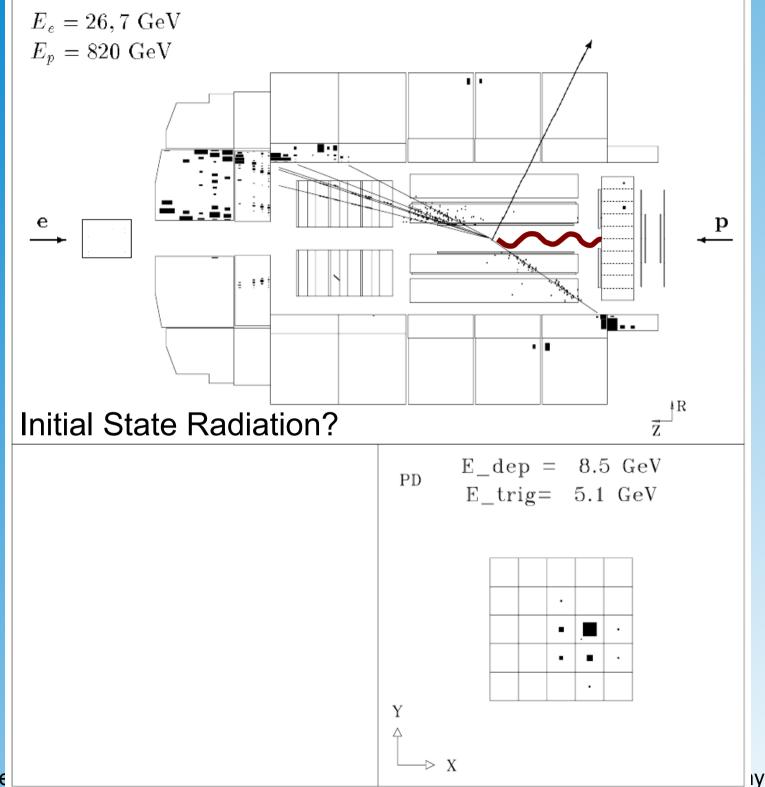

$$E-p_z$$
 (proton)=0 $E-p_z$ (electron) = 2 x 26.7 GeV

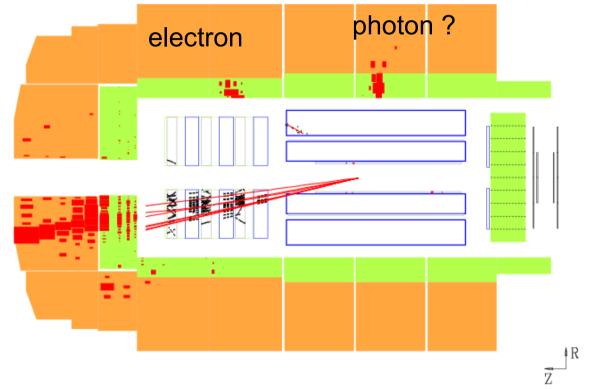

Kinematic Reconstruction of ISR

Photondetector at H1

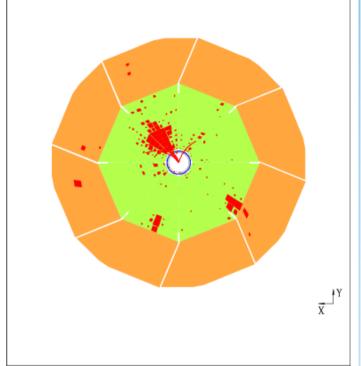

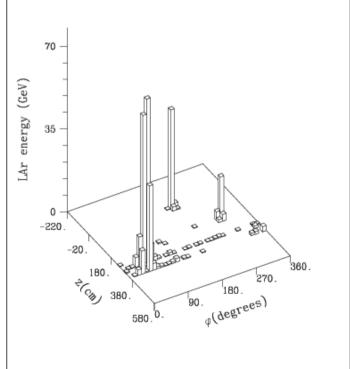

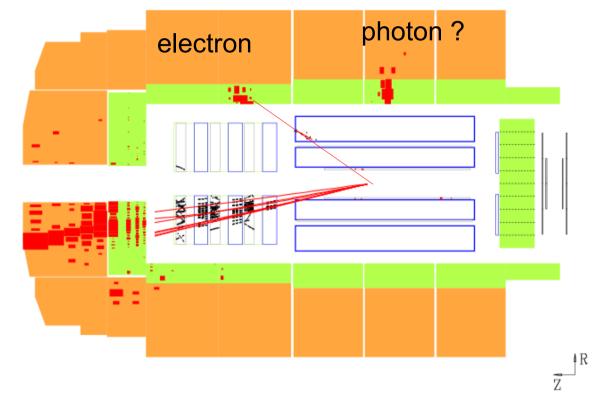

Inner Drift Chamber operational?

Final State Radiation?

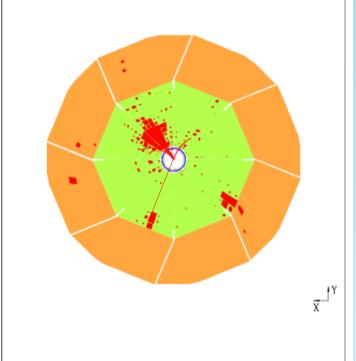

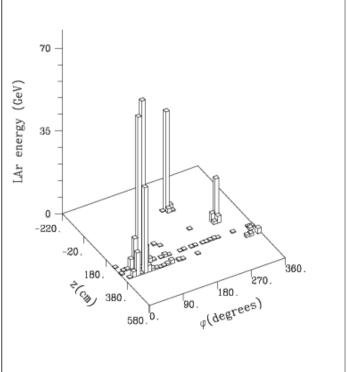

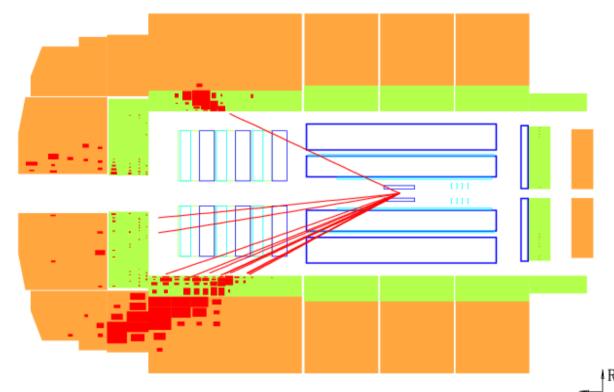

Inner Drift Chamber operational?

Final State Radiation?

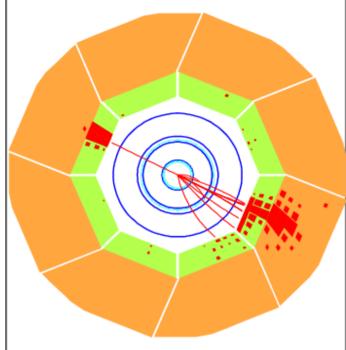

$$Q^2=25030~{
m GeV^2},~~y=0.56,~~M=211~{
m GeV}$$

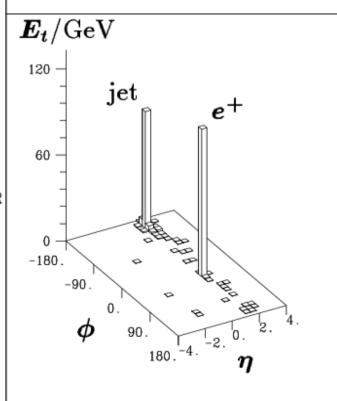

collinear photon can not be resolved!

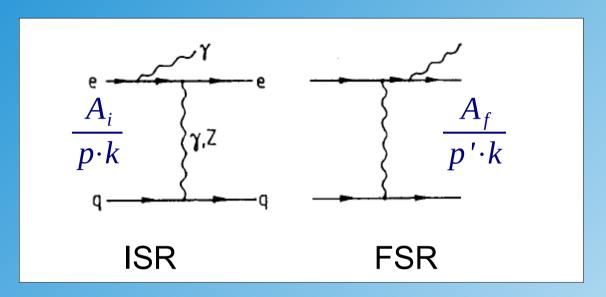

Radiative Poles

Neglecting the small electron mass, the poles become:

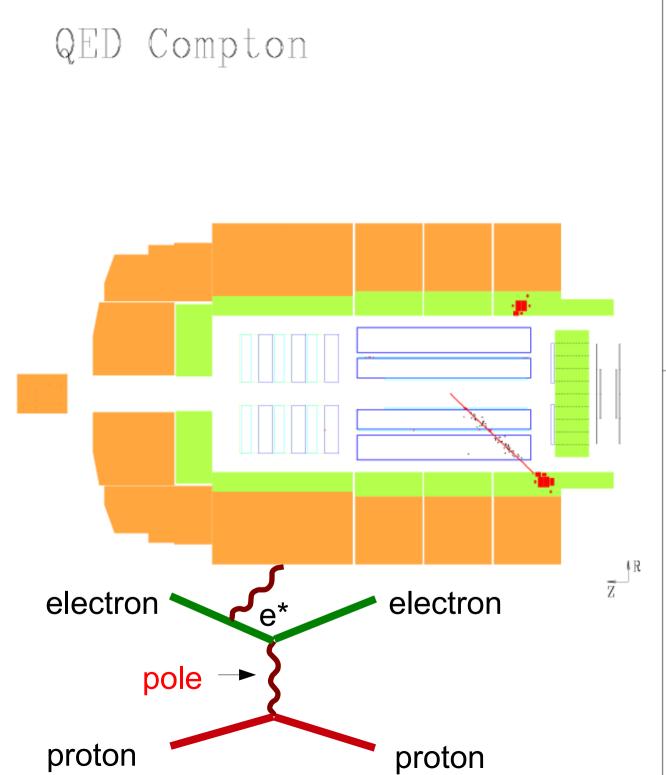

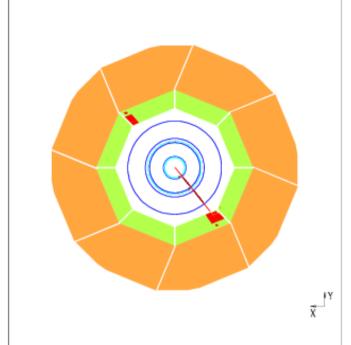

Note ISR reduces the available center of mass energy s^{1/2}

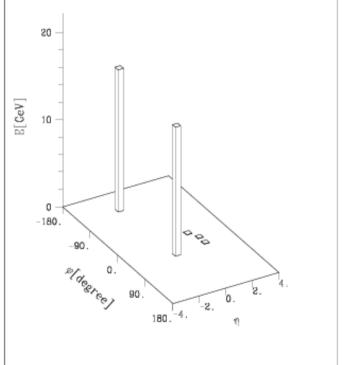

There is a third pole (Compton events / Wide Angle Bremsstrahlung):

$$\frac{A_c}{(p-p'-k)^2} = \frac{1}{q^2}$$
 (energy is transferred from the proton to the electron line)

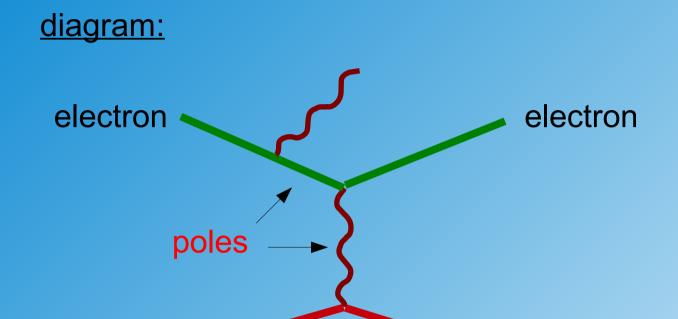

Final state electron and photon have large opening angles and are p_T balanced

Bethe Heitler Process

Cross section is largest if electron and photon are scattered (emitted) at small angle (Compton and ISR/FSR poles combined)

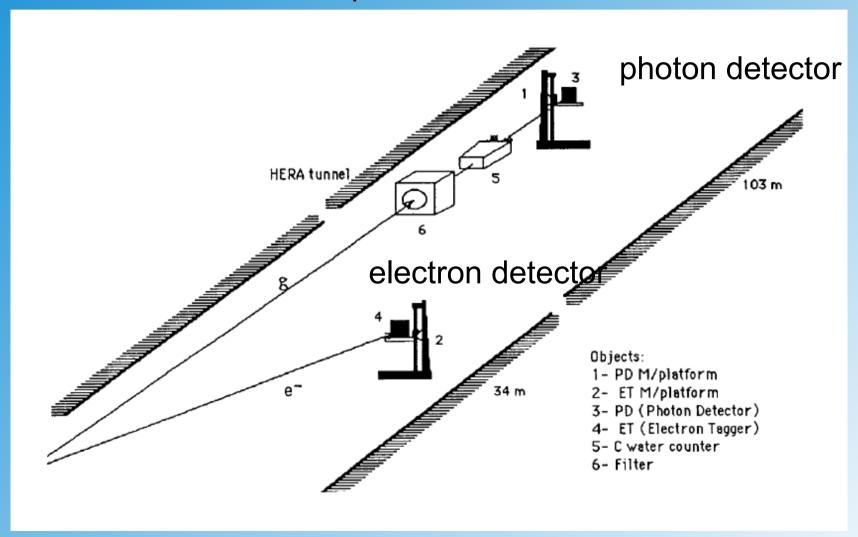

proton

Electron and photon go down the beampipe and are not registered in the central detector

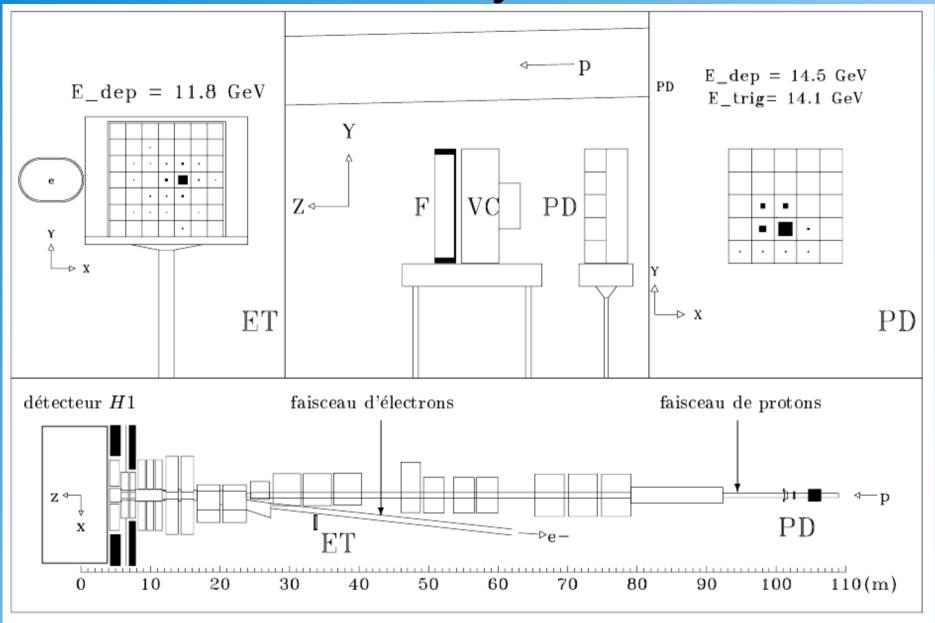

proton

Luminosity Measurement at HERA

dedicated electron and photon detectors

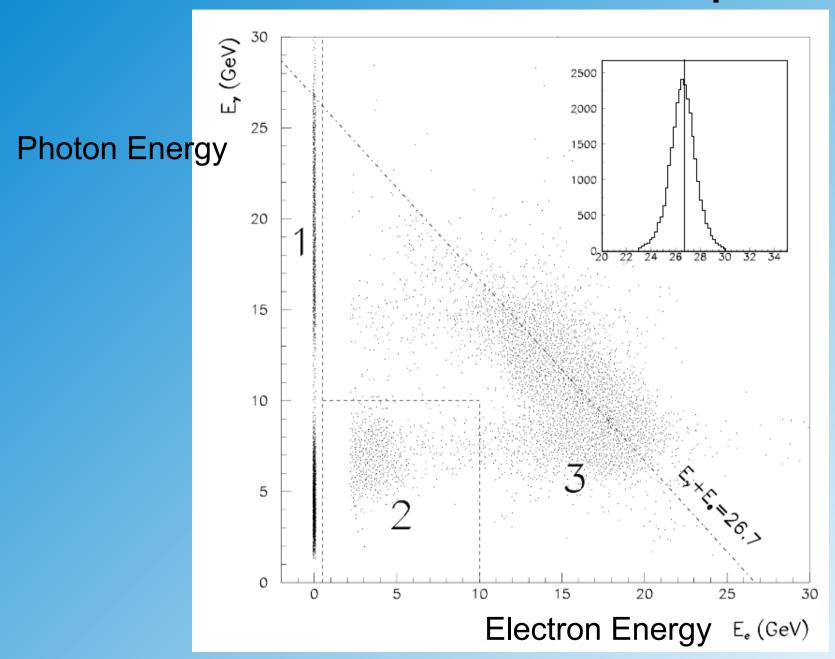

H1 Luminosity Detectors

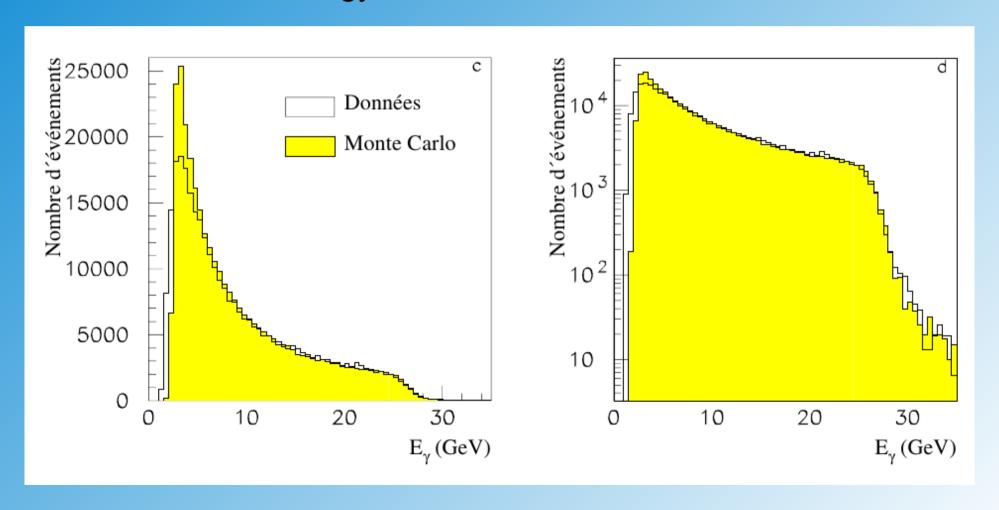

Method: measure coincidence signal

Coincidence Technique

Data Monte Carlo Comparison

Photon Detector Energy

Principle of Luminosity Measurement

Integration of the instantaneous luminosity:

$$\mathcal{L}_{b} = \int_{0}^{\Delta T} L_{b}(t) dt$$

Relation between Photon counts, Bethe-Heitler cross section and integrated Luminosity

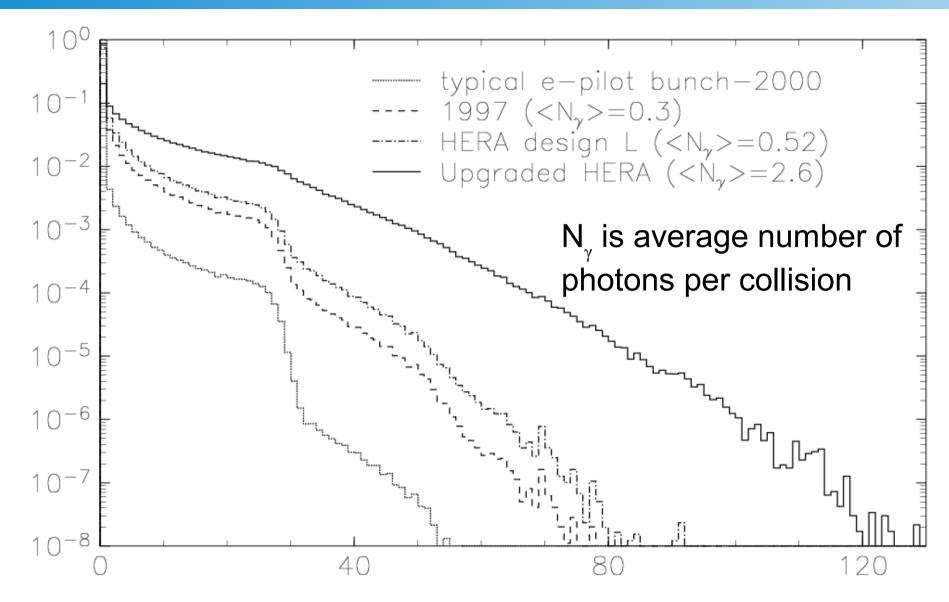

$$N_{\gamma}(E > \epsilon) = \mathcal{L}_{b} A \int_{\epsilon}^{\infty} \frac{\mathrm{d}\sigma_{BH}}{\mathrm{d}E} \mathrm{d}E$$

Breakdown of Systematic Errors

Item	Online Actual	Offline Actual	Online Upgrade
Theoretical uncertainty	0.5	0.5	0.5

	1.05%			

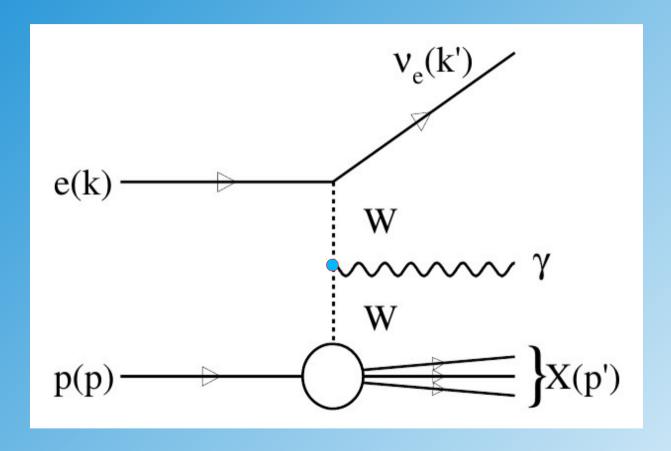

total systematic error [in percent]: $0.22^2 + 1.41^2 + 1.17^2 + 1.05^2 = 2.12^2$

Bremsstrahlung in Charged Currents

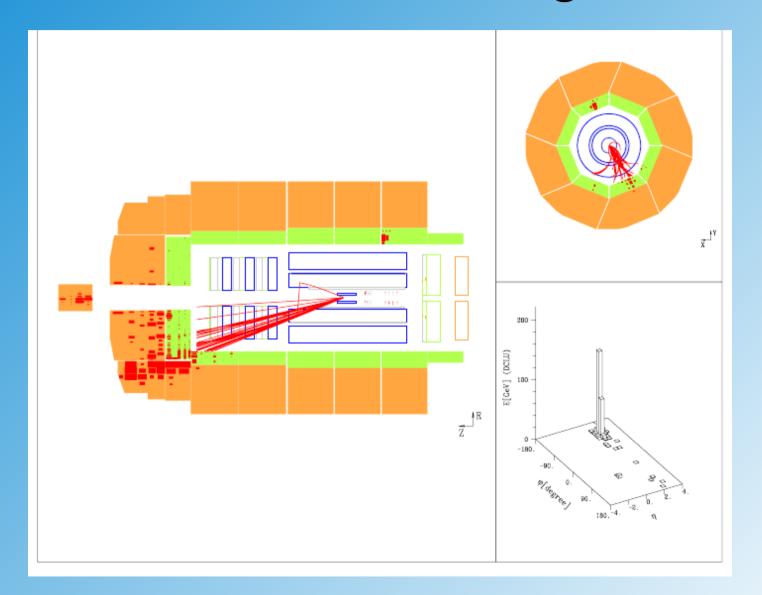

Neutrinos are note seen in detector and create missing p_T

Radiative Charged Current Events and W-W-γ Coupling

The W-boson is electrically charged and can also radiate photons! It is possible to test anomalous couplings

Charged Current Event with Bremsstrahlung

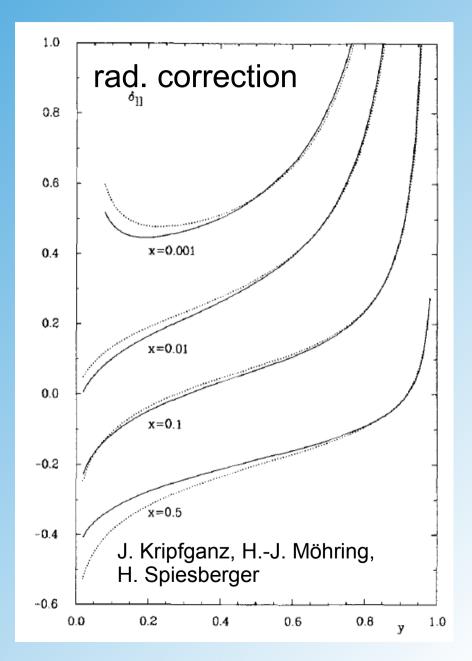

Radiative Corrections in CC events

Higher order leading logarithmic QED corrections to deep inelastic ep scattering at very high energies have significant impact on the kinematic reconstruction

These logarithmic QED corrections come from multiple photon emissions

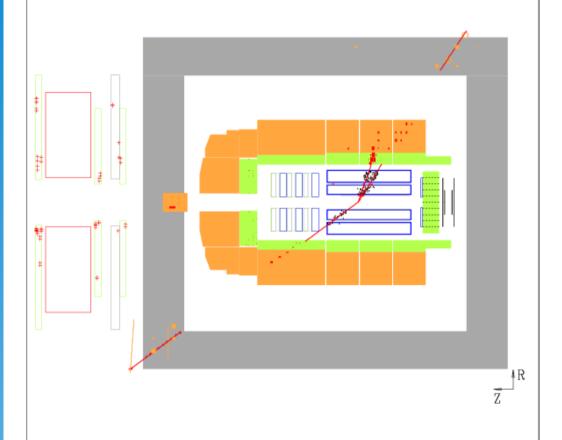

→ systematic error of precision measurements

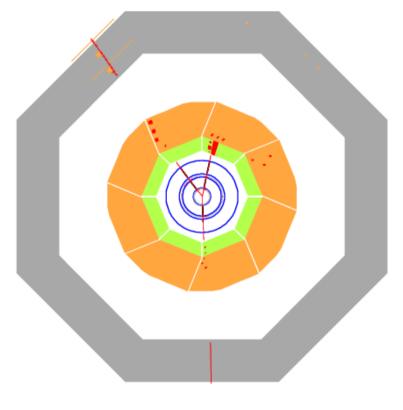

Higher Order Processes at HERA

e+ mu+ mu-

Alpha⁴ Processes at HERA

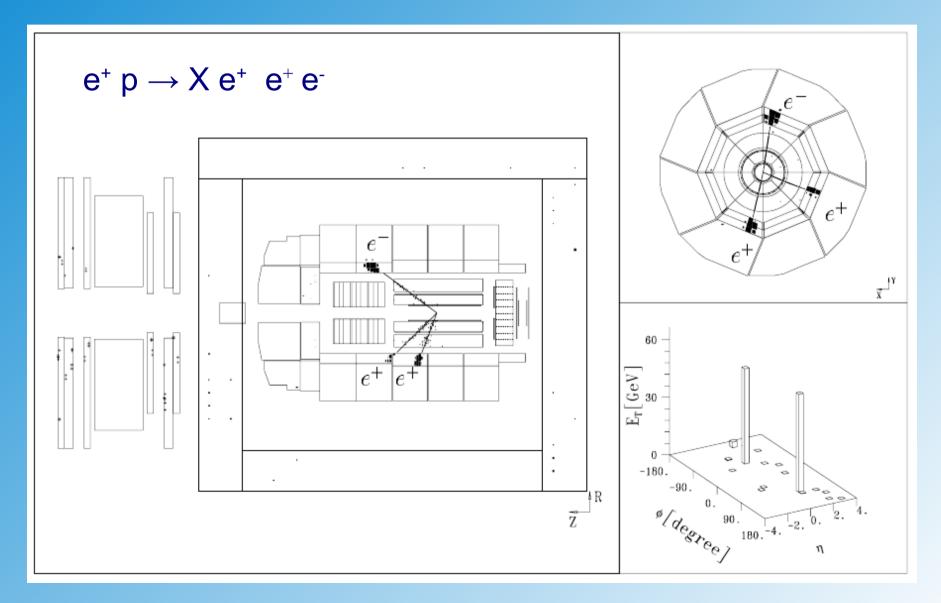

$$e^+ p \rightarrow e^+ X \mu^+ \mu^-$$

 \overline{X}^{Y}

Alpha⁴ Processes at HERA

Exploitation of ISR

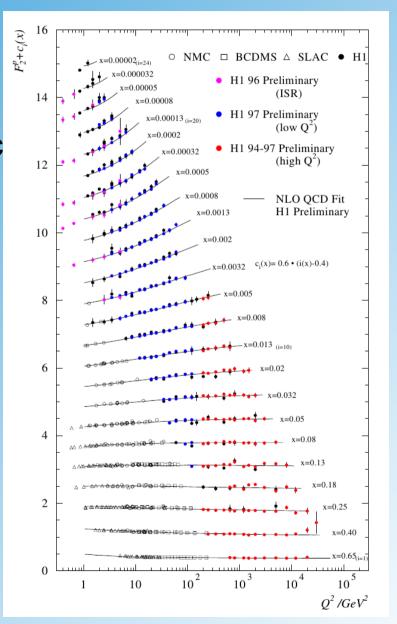

Exploitation of ISR

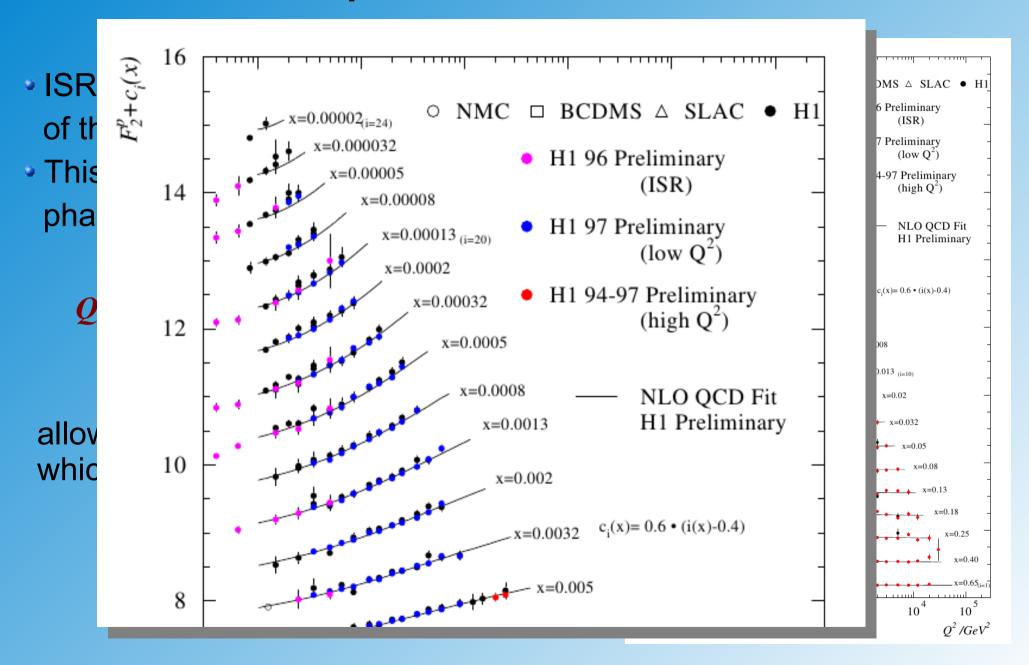

- ISR reduces the center of mass energy of the actual hard interaction
- This can be used to extend the kinematic phase space to lower energies

$$Q^2 = -q^2 = -(p-p')^2$$

allows to access smaller values of Q² which could not be reached otherwise!

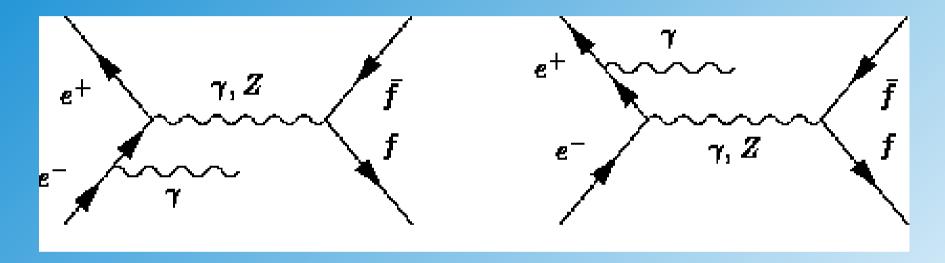

Exploitation of ISR

Radiative Returns

Z-boson are resonantly produced in e⁺ e⁻ collisions at resonance (m₇ ~91 GeV)

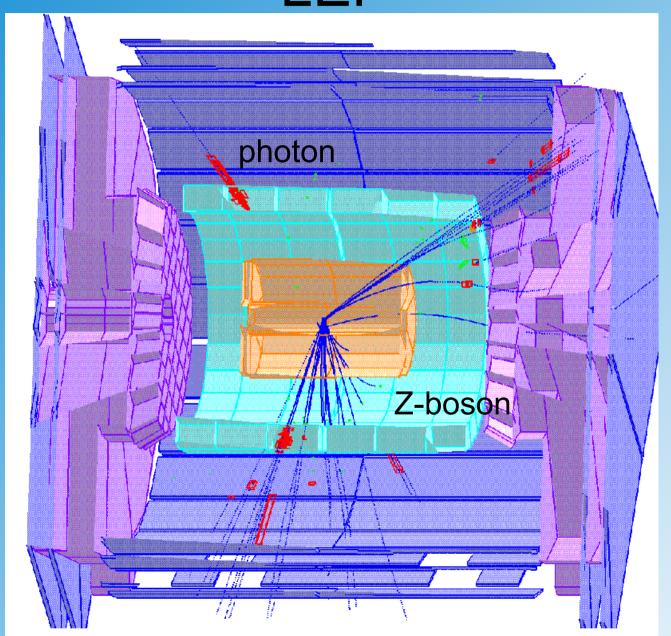

For $s^{1/2} > m_7$ the radiative return allows a return to the resonance:

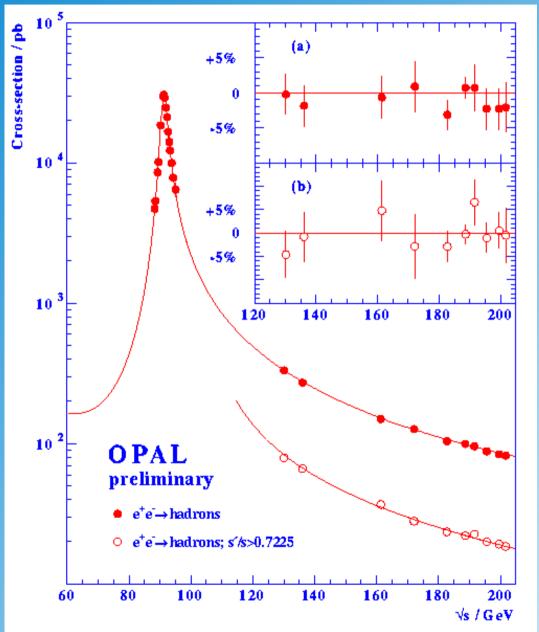

$$e^+ e^- \rightarrow Z \gamma$$

This effect can be large, e.g. at LEP

DELPHI Radiative Return Event at LEP

Measurement of Radiative Return

radiative returns are externely important!

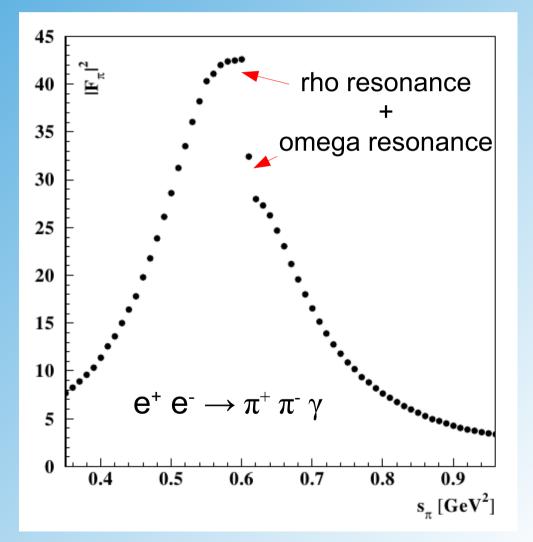

incl. radiative return

no radiative return

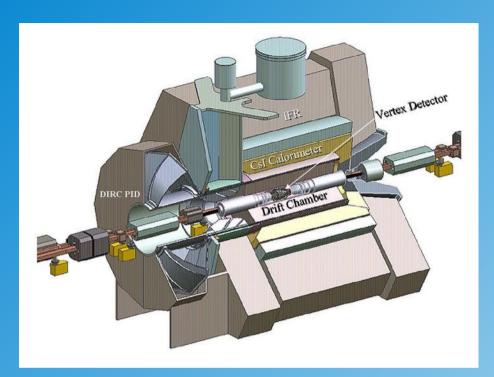

Radiative Return at KLEO (Daphne)

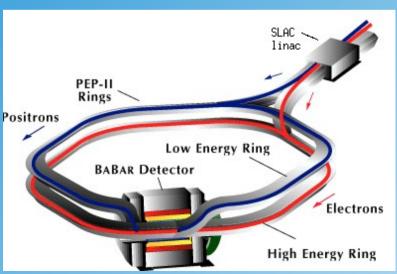

e⁺ e⁻ collider at s^{1/2} = 1 GeV

Radiative Returns at Barbar

 $e^+ e^-$ collider at $s^{1/2} = 10$ GeV $e^+ e^- \rightarrow p \bar{p} \gamma$
