- This corresponds to about 400 photons per cm³ with typical energy of $E_{\gamma} = kT_0 \simeq 2.3 \times 10^{-4} \text{eV} \simeq 150 \text{GHz} \ (\lambda \simeq 0.2 \text{cm})$. This is the observed CMB.

・ロト ・雪 ・ ・ ヨ ・ ・ ヨ ・

- The Universe is expanding. In the past it was much denser and hotter.
- At T > 3000K hydrogen was ionised and the 'cosmic plasma' of protons, electrons and photons was strongly coupled by Thomson scattering and in thermal equilibrium.
- At $T \simeq 3000$ K protons and electrons combined to neutral hydrogen. The photons became free and their distribution evolved simply by redshifting of the photon energies to a thermal distribution with $T_0 = 2.7255 \pm 0.0006$ K today.
- This corresponds to about 400 photons per cm³ with typical energy of $E_{\gamma} = kT_0 \simeq 2.3 \times 10^{-4} \text{eV} \simeq 150 \text{GHz} \ (\lambda \simeq 0.2 \text{cm})$. This is the observed CMB.
- At *T* > 9300K ≃ 0.8eV the Universe was 'radiation dominated', i.e. its energy density was dominated by the contribution from these photons (and 3 species of relativistic neutrinos which made up about 35%). Hence initial fluctuations in the energy density of the Universe should be imprinted as fluctuations in the CMB temperature.

Fluctuations in the CMB

$$T_0 = 2.7255K$$

$$\Delta T(\mathbf{n}) = \sum_{\ell m} a_{\ell m} Y_{\ell m}(\mathbf{n})$$

$$C_{\ell} = \langle |a_{\ell m}|^2 \rangle,$$

$$D_{\ell} = \ell(\ell + 1)C_{\ell}/(2\pi)$$

Polarisation of the CMB

Thomson scattering depends on polarisation. A local quadrupole induces linear polarisation, $Q \neq 0$ and $U \neq 0$. • In the radiation dominated Universe small density fluctuations perform acoustic oscillations at constant amplitude, $\delta \propto \cos(k \int c_s d\tau)$. On large scales, the gravitational potential (metric fluctuation) is constant, on 'sub-Hubble scales', $k\tau > 1$ it decays like a^{-2} .

・ロト ・回ト ・ヨト ・ヨト

- In the matter dominated Universe density fluctuations grow $\delta \propto a$ and the gravitational potential remains constant.
- On small scales fluctuations are damped by free streaming (Silk damping).
- In a Λ -dominated Universe δ is constant and the gravitational potential decays.

The angle onto which the scale k_* is projected depends on the angular diameter distance to the CMB, $\theta_* = \lambda_*/(2d_A(z_*))$ This is the best measured quantity of the CMB, with a relative error of about 3×10^{-4}

$$\theta_s = \frac{r_s}{d_A(z_s)} = (1.04077 \pm 0.00032) \times 10^{-2}$$
.

(Planck Collaboration: Planck results 2015 XIII)

イロト イヨト イヨト イヨト

The angle onto which the scale k_* is projected depends on the angular diameter distance to the CMB, $\theta_* = \frac{\lambda_*}{(2d_A(z_*))}$ This is the best measured quantity of the CMB, with a relative error of about 3×10^{-4}

$$\theta_s = \frac{r_s}{d_A(z_s)} = (1.04077 \pm 0.00032) \times 10^{-2}$$
.

(Planck Collaboration: Planck results 2015 XIII)

The distance to the CMB is given by

$$(1+z_*)d_A(z_*) = \int_0^{z_*} H(z)^{-1} dz = \frac{h}{H_0} \int_0^{z_*} \frac{1}{\sqrt{\omega_m(1+z)^3 + \omega_K(1+z)^2 + \omega_x(z)}} dz$$

イロト イヨト イヨト イヨト

Cosmological parameters

The CMB fluctuations into a direction ${\bf n}$ in the instant decoupling approximation are given by

$$\frac{\Delta T}{T}(\mathbf{n}) = \left[\frac{1}{4}D_g + \mathbf{n}\cdot\mathbf{V} + \Psi + \Phi\right](\mathbf{n},\tau_*) + \int_{\tau_*}^{\tau_0} \partial_{\tau}(\Psi + \Phi)ds.$$

The power spectrum C_{ℓ} of CMB fluctuations is given by

$$\left\langle \frac{\Delta T}{T}(\mathbf{n}) \frac{\Delta T}{T}(\mathbf{n}') \right\rangle = \frac{1}{4\pi} \sum_{\ell} (2\ell+1) C_{\ell} P_{\ell}(\mathbf{n} \cdot \mathbf{n}')$$

- Inflation is a phase of very fast expansion during which the Universe becomes large and flat. This can be achieved with the energy density of a scalar field if it is dominated by the scalar field potential, V.
- When inflation ends the inflaton field decays into the standard model particles which thermalize and generate a hot thermal Universe.

・ロ・・ (日・・ 日・・ 日・・

The fluctuations in the CMB stem from a very early phase of inflationary expansion of the Universe. They contain inform, ation on the physics of this very hot early phase.

- Inflation is a phase of very fast expansion during which the Universe becomes large and flat. This can be achieved with the energy density of a scalar field if it is dominated by the scalar field potential, V.
- When inflation ends the inflaton field decays into the standard model particles which thermalize and generate a hot thermal Universe.
- During inflation quantum fluctuations of both, the inflaton and of the metric are stretched and amplified.

Inflation

Once a quantum mode 'exits the horizon' $\lambda > H_*^{-1}$, they 'freeze in' as classical fluctuations of the energy density and of the metric with a nearly scale invariant spectrum.

Or even simpler: A wave function scatters at a time dependent potential and gets amplified.

.

Inflation

Slow-roll inflationary models can be described with a few (mainly 2) slow-roll parameters and the Hubble scale during inflation, H_* . The scalar and tensor spectra from inflation are given by

$$P_{\zeta}(k) \simeq \frac{H_*^2}{\epsilon M_{\rho}^2} k^{-6\epsilon+2\eta} \simeq 12.2 \times 10^{-9} \qquad P_h \simeq \frac{H_*^2}{M_{\rho}^2} k^{-2\epsilon} \simeq \left(\frac{E_*}{M_{\rho}}\right)^4$$
$$E_* = \left(\frac{r}{0.1}\right)^{1/4} 1.7 \times 10^{16} \text{GeV}$$
