

GERDA meeting

Ringberg castle, 11 Febr 07

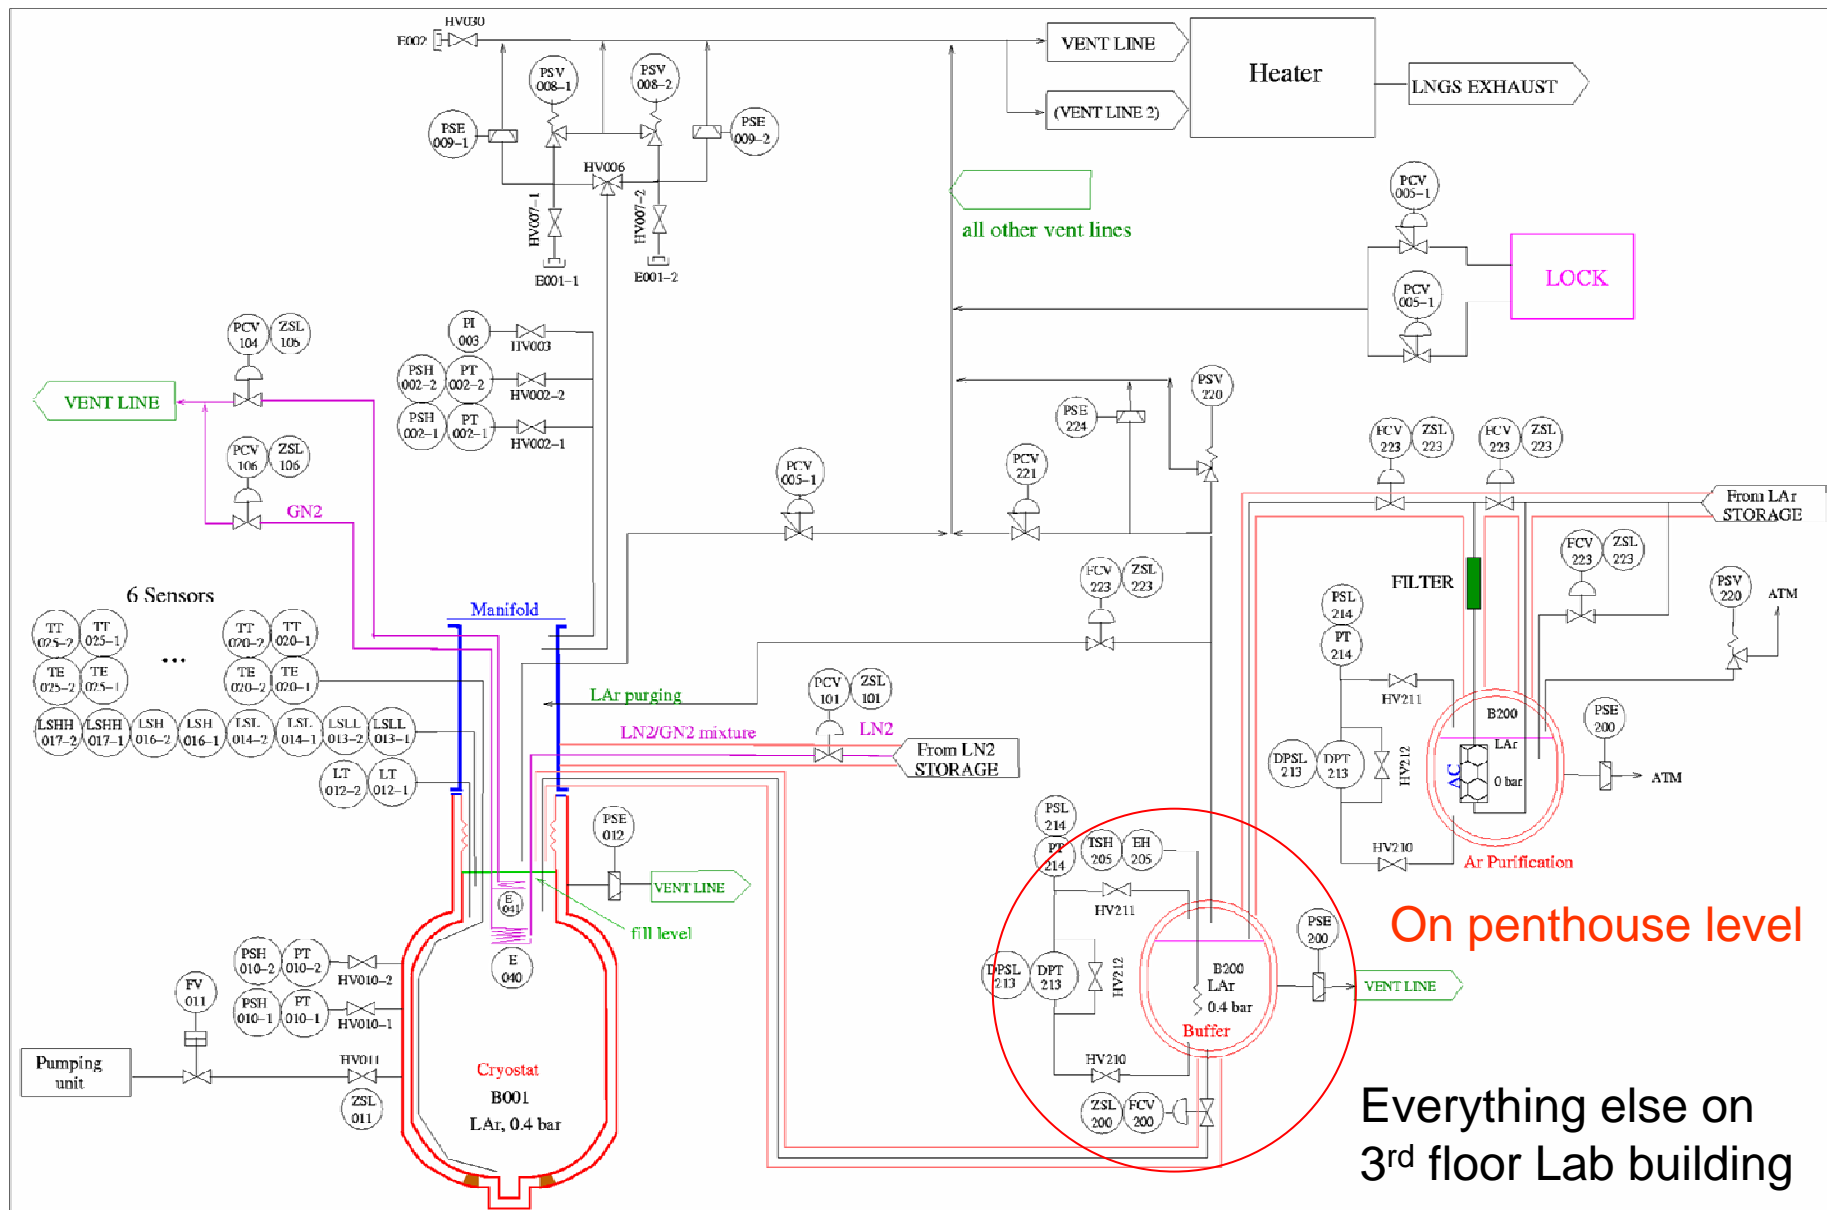

# Cryogenic Infrastructure

Bernhard Schwingenheuer  
MPI Heidelberg

# Outline

- Update on PID
- Pipes and Connections
- Valve specifications
- Active cooling
- Radon trap
- Heater
- Level sensors
- Summary

# Piping & Instrumentation Design

# Pipes and Connections

Basic idea: use “flexible” superinsulated pipes for all LAr & LN2 transfer lines

Example: for 1 m<sup>3</sup>/h need ID=30, OD=58 pipe,  
 $\Delta p=0.3$  bar for 40 m length,  
bending radius = 500 mm  
connections: customer specific,  
e.g. Johnston coupling

Production: sheet is cleaned before welding,  
no grease for forming at the inside,  
no cleaning at the inside needed

Connections at end of pipe:  
Safety valve,  
Vacuum pumping port  
Gauge measurement port

price is similar to  
non-flexible pipe with  
flexible sections,  
easier installation at LNGS

# Johnston coupling

PTFE seal with internal spring for horizontal orientation of coupling

flange with metal seal, e.g. CF for Rn tightness

for horizontal orientation:  
PTFE seal blocks LAr to reach  
the warm flange

galvanic decoupling possible at Johnston connection

# Valve specification

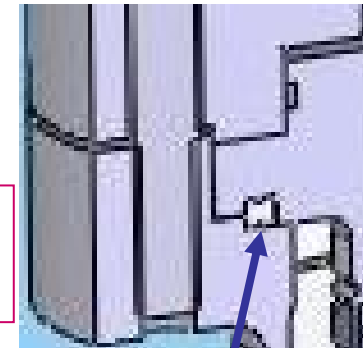

- for LN2 active cooling:  
no special requirements
- for LAr: metal seal to atmosphere  
( $< 10^{-7}$  mbar\*l /s)  
metal seat due to charcoal particles  
( $< 10^{-5}$  mbar\*l/s)
- for GAR: soft seat for tightness to atm.  
( $< 10^{-7}$  mbar\*l/s)  
metal seal to valve body  
( $< 10^{-7}$  mbar\*l/s)

need some equal percentage control valves  
→ order same type everywhere

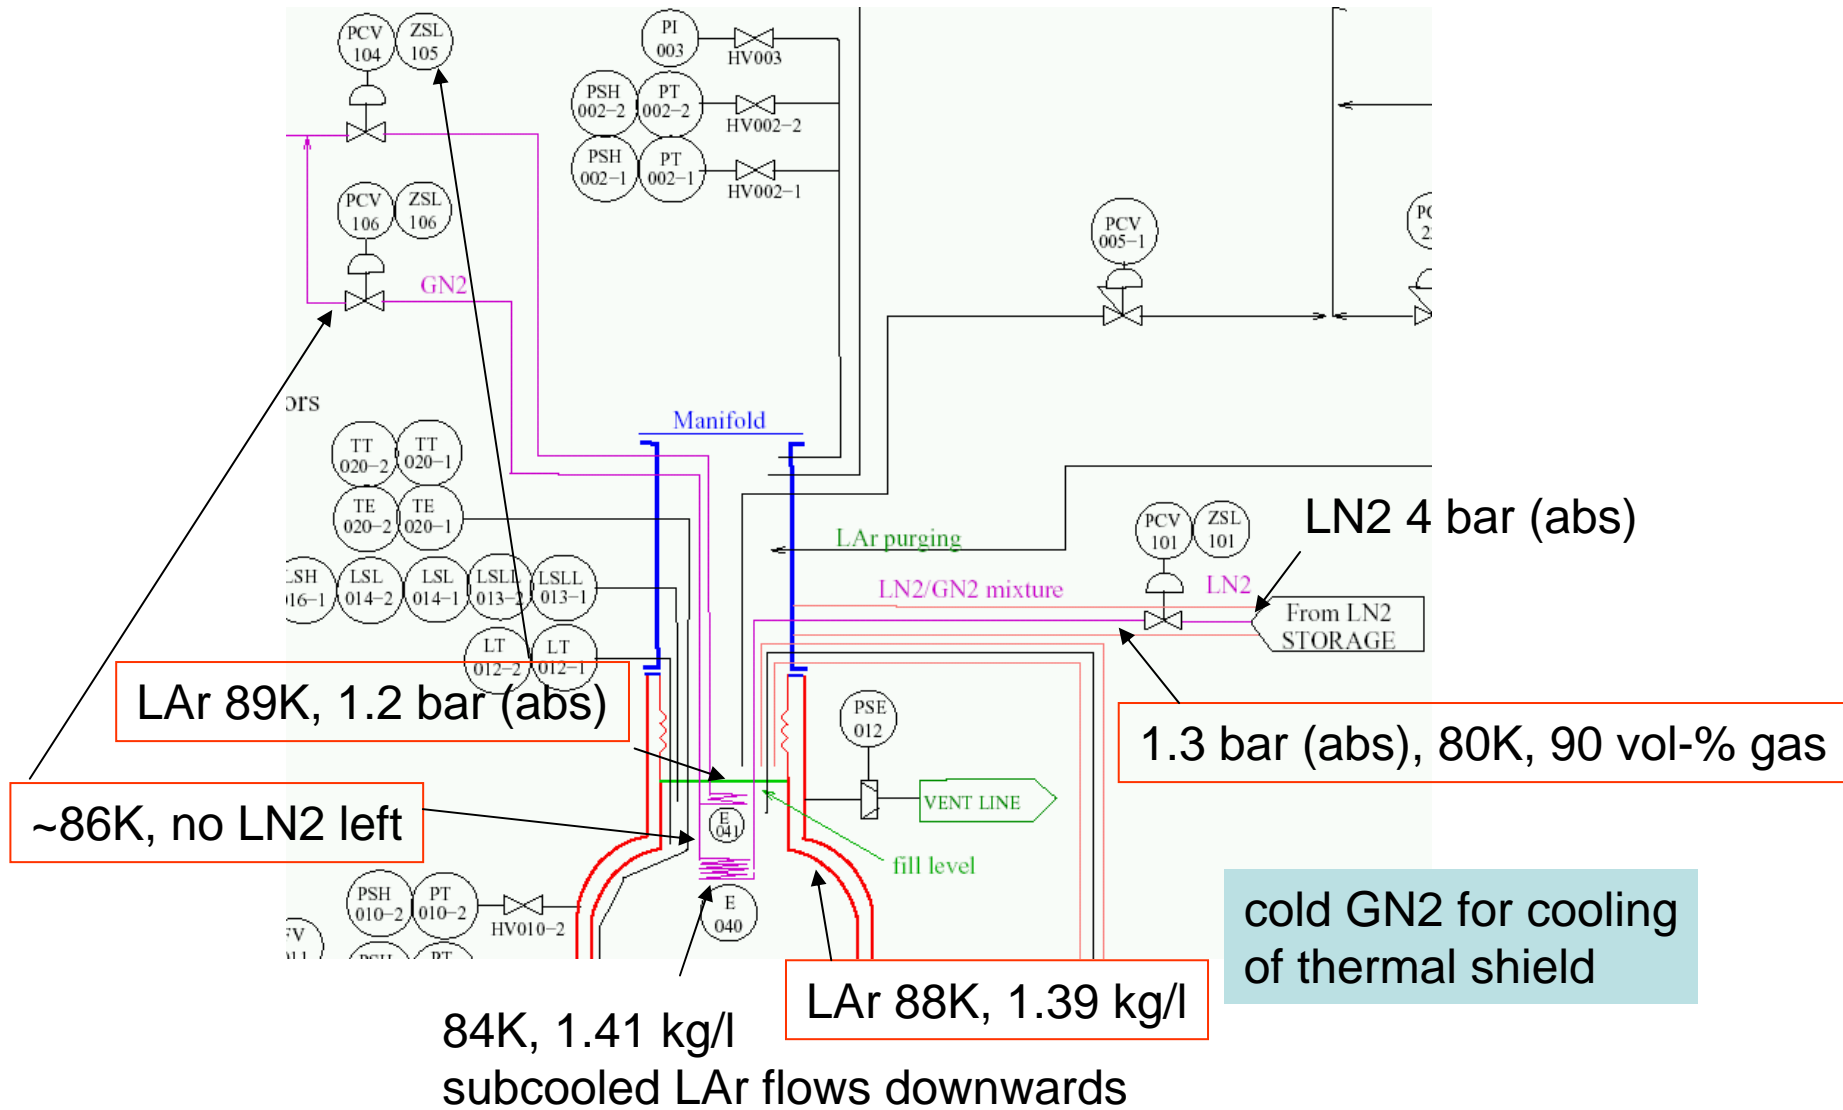

companies are very helpful, provide test valves  
for Rn diffusion measurement ...

special GERDA design with Cu ring and cutting edges

specification advanced, valve diameters calculated, tendering could start soon

# Active cooling

## Dimension heat exchanger:

- from boiling curve LN2: heat transfer coefficient  $\sim 300 \text{ W}/(\text{m}^2 \text{ K})$
- GN2/LN2 has temperature of 80 K at inlet heat exchanger
- LAr should be cooled to 84 K (above freezing point)
- $\sim 1 \text{ m}^2$  area for heat exchanger is enough

## Valve control in LN2 / GN2 circuit:

- at input to reduce pressure to 1.3 bar (abs) → 90 vol-% gas
- at output of 2<sup>nd</sup> heat exchanger controlled by pressure in cryostat  
→ determines operating point of cryostat, 0.2 bar overpressure
- at output of 1<sup>st</sup> heat exchanger controlled by temperatures:
  - GN2 at outlet
  - LAr below heat exchanger
  - LAr close to heat exchanger to avoid freezing of LAr
  - regulates cooling power of main heat exchanger

## Challenge:

valves affect each other, need different time constants for PI(D) regulators

dimensioning (almost) finished, test in our “prototype neck” foreseen

# Radon trap & thermal shield

GAr purge flow too small to purge Rn coming out of cables,... → need Rn trap

Sketch for a radon trap = cold surface

current preferred solution:  
no thermal shields in the middle,  
diameter ~ 500 is open  
→ 100 Watt thermal loss

add thermal shield between  
diameter 500 and 800,  
active cooling for LAr should also  
cool one layer of the shield

# Exhaust gas heater options

DN 300 tube fixed to cable trays of Muon Veto  
3 turns inside the water tank → 100 m<sup>2</sup> surface  
(for heating 10000 m<sup>3</sup>/h cold Argon gas to 5 °C)

prefabricated parts with flanges (water tight seal enough)

rectangular tube (140x500) on the OUTSIDE of the water tank,  
6 turns → cover 100 m<sup>2</sup> outer surface

welded (or even screwed), some small leaks tolerable,  
thin material (1 mm) should be enough (almost no overpressure),  
no interference with muon veto, no (little) interference with  
schedule, no feedthrough in water tank roof

prices for the two solutions not yet investigated

# Level sensors

For initial filling of cryostat: 6 Pt-100 sensors (1/m fill level), switched off later  
in the neck: want two independent level measurements with ~10 cm resolution

## WEKA Level measurement

analog  
output 4..20 mA

swimmer  
with magnet

tube with  
REED contacts  
on PCB inside

- Pt-100 sensors at different height  
(problem due to active cooling (cold gas)?  
bad experience at test cryostat and Rn traps)
- hydrostatic pressure? NO, needs warm pipe  
in vacuum volume
- ultra sound? (reflectivity at LAr & sound speed  
variation with T)
- radar (100 MHz – 1.5 GHz, specified at 77 K,  
interference with Ge measurement?)
- capacitive? (interference with Ge?)
- swimmer and REED contacts a la WEKA?  
not specified but first tests show that it can work

# Summary

- Progress has been made for the specification of entire cryo infrastructure (valves, pipes, ...), but slower than expected in Nov 06 (no tendering yet)
- still some open issues: rupture disk, level sensor,...
- many thanks to Mr Perinic (CERN),  
Mr Haberstroh (Dresden)
- possibly make a decision concerning  
the heater &  
galvanic decoupling between infrastructure & cryostat
