

The XMASS Dark Matter Experiment in Kamioka, Japan: Status and Results

Kai Martens
Kavli IPMU
The University of Tokyo

Outline

- **Kavli IPMU:** introducing the institute
- **Dark Matter:** setting the stage
- **Kamioka Observatory:** the preeminent underground science laboratory in Japan
- **XMASS Experiment:**
 - design
 - status
 - first results
 - future plans
- (if time allows:
 - Liquid noble gas cleanup...)

INSTITUTE FOR THE PHYSICS AND
MATHEMATICS OF THE UNIVERSE

one of the 5 original WPI centers:

- founded Oct. 1, 2007
- first institute in Todias Jan. 11, 2011
- first Kavli institute in Japan May 10, 2012

best evaluations among WPI centers...

Mandates:

(Solicitation 2007/03):

- secure research funding matching WPI funding ✓
- > 30% non-Japanese ✓
- > 200 staff members ✓
- globally visible like Max-Planck, IAS, IHES
with their long traditions

ministerial funding: 10(+5) years... Todai:

review criteria: science, globalization,
interdisciplinary research, **organizational reform**

**members have to be outside
of Japan for 1-3 month/year**

- We of course are aware this is not a true indicator of the “impact” of an institution, but in the absence of any better alternative:

institute	IPMU	IAS	KITP	YITP	Perimeter	ICTP
citation/ paper	7.6	7.3	8.1	6.5	9.6	4.5
#papers >50 citations	8	18	8	3	13	4

- We have provided an additional report on mathematics for more detailed review

Thomson Reuters, excluding reviews
fields: astronomy, astrophysics, particle and fields,
multidisciplinary physics, mathematics, applied mathematics

**@ 3rd anniversary
(Oct. 2010)**

Early Observations: Oort & Zwicky

1932: Jan Oort (Leiden, Netherlands):

“measures” matter in galactic disk near sun from motion of **nearby stars**: $1M_{\odot}/375\text{ly}^3 > 2m_{\text{stars}}$

→ **dark matter**

Vera Rubin @ Carnegie Institution of Washington:
rotation curves of galaxies
1975 AAS meeting
1980 paper

1933: Fritz Zwicky (Caltech, **USA**):

virial theorem: $\Sigma T = \frac{1}{2} \Sigma U$
→ **galaxies in Coma cluster**
too fast for cluster's gravitational potential

→ **dark matter**

Dark Matter: It's out there ...

So What Are We Looking For?

- **gravitating:** ...
- **cold:** → **massive** ← if particle ...
- **collisionless:** → **no E/M interaction**
→ **no strong interaction**
at most: weakly interacting ???

New Scientist (2005/03/19): Michael Brooks: 13 things that do not make sense:

Maybe we can't work out what dark matter is because it doesn't actually exist. That's certainly the way Rubin would like it to turn out. "If I could have my pick, I would like to learn that Newton's laws must be modified in order to correctly describe gravitational interactions at large distances," she says. **"That's more appealing than a universe filled with a new kind of sub-nuclear particle."**

(Rubin as in: Vera Rubin)

favorites are: **neutralino, axion, Kaluza-Klein, gravitino**

Dark Matter and the WIMP Miracle

WIMP denomination $\rightarrow$ weak interaction ...

WIMP decoupling after BB:

velocity averaged
annihilation cross-section
for **GeV-TeV mass WIMPs**:

$$\langle \sigma v \rangle = 3 \times 10^{-26} \text{ cm}^3/\text{s}$$

$\rightarrow$ correct DM density

TeV $\sim$ SUSY partners ?!?
 $\rightarrow$ **miracle ...**

WIMP Dark Matter Searches: Direct Detection

important for verification:
different target materials
→ consistency!

two types of interaction:

- spin dependent (odd isotopes), smaller cross section
- spin independent; $\sigma \sim A^2$ (coherent: whole nucleus)

Hints of Low Mass WIMPs

DAMA/Libra: 250kg NaI(Tl), scintillation
13 years of measurement

CoGeNT: 440g p-type Ge detector, ionization
442 live days

CRESST-II: 8x300g CaWO₄, scintillation + phonon
730kg/d

The Current Situation:

(WIMP hypothesis:)

compatible:

- spectra:

CoGeNT/CRESST-II

- modulations:

DAMA/CoGeNT

tension:

- Xe/all of the above

- modulation amplitude
(halo assumptions...)

The Kamioka Observatory: new: KAGRA

KamLAND (Xe)

CANDLES

XMASS

IPMU
Lab

EGADS

NEWAGE

CLIO

2km to exit

3km to Mozumi

IPMU Lab:
U, Th → HP-Ge ← few 100ppt
→ ICP-MS ← 1ppq*
Kr → API-MS ← 1ppt*
* after concentration

Legend:

DM, ν , $\beta\beta$, GW

The XMASS Experiment

Xe detector for weakly interacting **MASS**ive particles
Xe ν -**MASS** detector
Xe **MASS**ive ν -detector

Exploiting **X**enon:

- high mass number $\rightarrow$ **SI** cross section
- no long-lived radioactive isotope
- good scintillation yield: $\sim 46\text{ph/keV}$
- high density (liquid): 3g/cm^3
- 48% odd isotopes (natural) $\rightarrow$ **SD** cross section
- $\beta\beta$ candidate: $^{136}\text{Xe} \rightarrow ^{136}\text{Ba} + 2e + 2.48\text{MeV}$

Ultimately: 10t fiducial volume multi-purpose detector:

- neutrino mass: $\beta\beta$
- Dark Matter: WIMP limited by:
- solar neutrinos: $\text{pp}, ^7\text{Be}$

(water tank in Hall C designed to hold this...)

XMASS Progression:

the far future:

the current incarnation:
800kg WIMP detector
(100kg fiducial), 80cm

the PAST:
100kg **prototype**,
(3kg fiducial), 30cm
proof of principle

100kg reference:
arXiv:0912.2405

the next step:
5 ton total, > 1.5ton fiducial

24t, $\beta\beta + \nu_{\odot}$
(10t fiducial)
2.5m

detector technology
advantages:

- simple
- scalable
- self-shielding

ultimately: 24t (10t fid.) 2.5m ???

sampling rate 1GS/s
resolution 10bit
 $1.2\ \mu\text{s}$ window

Low BG PMT Development:

BG: biggest worry → PMT

great development:

$$U < 1.0$$

$$Th < 0.94$$

$$K < 9.68$$

$$Co = 4.47 \pm 0.34$$

630 hexagonal + 12 round) PMTs:

Hamamatsu R10789: QE 28-39%

+

XMASS photocathode coverage: 62.4%

Xe Distillation: ^{85}Kr Removal

otherwise:

extensive materials validation
before construction:

IPMU Lab:

U, Th → HP-Ge ← few 100ppt

→ ICP-MS ← 1ppq*

Kr → API-MS ← 1ppt*

* after concentration

experience:

detector stable w/o:

- routine getter operation
- active Rn removal

hall C distillation system:
(used before filling detector)

K.Abe et al,
Astroparticle Physics
31(2009), p290

capacity of XMASS Xe distillation system:
6kg/h; did 1 ton in ~ 1 week → $(3.3 \pm 1.1)\text{ppt}$

XMASS Calibration System:

“internal” γ calibration for XMASS:

- ^{57}Co (122keV) $\leftarrow$ main anchor of energy scale
- ^{241}Am (59.5keV), ^{109}Cd (88keV), ^{55}Fe (5.9keV)

“external” (hose)

- ^{60}Co , ^{137}Cs
- ^{252}Cf neutron calibration (needs FADC)

^{57}Co Calibration:

center position sets
energy scale:

→ 14.7 p.e./keV_{ee}

resolution 4% rms

reconstruction:
data

MC

@ center:
data vs. MC

BG: The Likely Culprits:

unexpected BG observed
from “surface between” PMTs:

α, β from “local” materials ?!

Al seal for PMT window:

^{238}U and ^{210}Pb (not in secular equilibrium)

Gore-Tex (light barrier) under PMT rim:
may contain up to
6% modern carbon

Background and Its Sources 1:

higher energies (0.1-3MeV):

understood: γ from PMTs
consistent w/Ge

histogram: data

MC: ^{210}Pb on Al

MC: PMT gammas

mid energies (5keV-1MeV):

understood: α, β on surface
consistent w/Ge

Background < 5keV (XMASS design thres.)

under study ...

one hypothesis:

some ^{14}C in Gore-Tex???
(modern carbon)

if so:

what assumption about
light propagation and
generation INSIDE the
Gore-Tex material???

shown: two assumptions:

both: generation: LXe
top: 0.3mm att. length
bot: 0.1mm att. length

wrong tree? (as in: barking up the ...)

histogram: data

MC: ^{210}Pb on Al

MC: ^{14}C in Gore-Tex

The Good News: BG (Low), LY high

(still optimizing: reduce leakage of surface events into FV)

but:

graph (- XMASS...)
taken from:
E. Aprile
(Princeton 2010)

cum grano salis:

high light yield (LY) → low threshold → go for light WIMPs

(heavy WIMPs → large A → large cross section → to come)

Light WIMPs: Full Volume, Low Threshold

playing to our strength:

full volume = 835kg
4 hit threshold = 6.8 days

our limit:
maximally allowed
cross section:
MC prediction < data

backgrounds considered:

- no OD activity →
- no afterpulse activity →
- Cherenkov (^{40}K in photocathode) →
- ringing, radioactivity →

cuts applied:

ID trigger only
timing RMS < 100ns
 $q(20\text{ns})/q(\text{total}) < 0.6$
 $\pm \Delta t > 10\text{ms}$

systematics accounted for:

L_{eff} , energy resolution & scale, trigger efficiency, cuts

Cherenkov Cut

Cherenkov light emission in PMT glass (^{40}K , ...)

Cherenkov photons emitted “immediately”:

→ timing structure by PMT timing resolution ($\sim 3.5\text{ns}$)

scintillation events:

→ time constant $\tau \sim 25\text{ns}$ (low energy γ and nucl. recoil)

cut parameter:

charge(first 20ns)
charge(total)

keep < 0.6

efficiency varies with p.e. range: 40% – 70%

XMASS Full Volume (835kg): Low Mass WIMPs

data set: 6.8 days of low threshold data

XMASS Result 1:

systematic contributions: (in order of importance)

- L_{eff} uncertainty *
- energy resolution
- trigger efficiency
- energy scale
- Cherenkov cut

*** following arXiv 1203.1589 (Xe100)**

XMASS Full Volume (835kg): Pseudoscalar by Axioelectric Effect

originally pursued to explain DAMA vs. nucl. recoil;

$$\text{rate: } R[\text{kg}^{-1}\text{d}^{-1}] = 1.2 \times 10^{19} \text{A}^{-1} g_{a\bar{e}e}^2 m_a p \sigma_{pe}$$

but: photoelectric cross section $\sigma_{pe} \sim 1/v \dots$

Prospects with Fiducialization:

high light yield allows
lower threshold

DATA listed top to bottom on plot
DAMA/LIBRA 2008 3sigma, no ion channeling
WARP 2.3L, 96.5 kg-days 55 keV threshold
CRESST 2007 60 kg-day CaWO₄
Edelweiss II first result, 144 kg-days interleaved Ge
ZEPLIN III (Dec 2008) result
XENON10 2007, measured Leff from Xe cube
CDMS: Soudan 2004-2009 Ge
Trotta et al 2008, CMSSM Bayesian: 68% contour
Trotta et al 2008, CMSSM Bayesian: 95% contour
Ellis et. al Theory region post-LEP benchmark points
Baltz and Gondolo 2003
Baltz and Gondolo, 2004, Markov Chain Monte Carlos
100315231700

... still working on “surface leakage” ...

Refurbishment:

in preparation:

- latter half of this year

lines of attack:

- Cu surface cleanup → electropolish to “rm -r U* Th*”
- light barrier (Cu cover) for PMT Al seal ← MC study
- remove Gore-Tex (presumed guilty until proven innocent ...)

Conclusions

XMASS 800kg completed first commissioning phase:

- exceptional light yield: 14.7 PE/keV_{ee}
- still analyzing data (stay tuned...)
- backgrounds largely understood

preparing for detector refurbishment:

- surface cleaning
- modification of inter-PMT spaces

→ resume data taking with reduced surface BG
& **FADC** - early next year.

**Results (so far): light WIMP limit, axio-electric cross section limit
more to come → stay tuned...**

also:

Starting to plan for 5 ton version of XMASS: XMASS 1.5

On Rn Removal from Liquid Phase

tested: charcoal trap (NIM A 661 (2012) p. 50-57)

new idea: charge sweep

from:
<http://www.pd.infn.it/~conti/LXe.html>
original Werner F. Schmidt

in **solids**: atoms in lattice
→ electron/hole **trapped**
in **fluids**: atoms moving
→ “ions” **drifting**

Info from Relevant Literature:

Radiation Phys&Chem 74 (2005) 152: The mobility of positive and negative ions in liquid xenon (W.F. Schmidt, O. Hilt et al.)
→ TMSi⁺: 8cm/s @ 40kV/cm , O₂⁻ 10cm/s @ 15kV/cm

NIM A 555 (2005) 205: Mobility of thorium ions in liquid xenon (K. Wamba et al.) → ion drift 1cm/s @ 4kV/cm

thesis Oliver Hilt:

Electronische und ionische Leitungsprozesse in flüssigem Xenon

Hole Drift and LXe Flow:

(holes would likely be relevant for Rn removal...)

hole mobility @ 170K: $3.7 \times 10^{-3} \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$
electric field strength: 3 kV/cm $\rightarrow v_{h+} = 11 \text{ cm/s}$

positive ion mobility: $\sim 0.1 \times 10^{-3} - 0.2 \times 10^{-3} \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$ $\rightarrow v_{l+} \sim 0.5 \text{ cm/s}$

cleaning volume: $1 \text{ cm} \times 4 \text{ cm}$ cross section,
 $1 \text{ l/min} = 1000 \text{ cm}^3 \text{ /min}$; 4 cm^2 cross section $\rightarrow$ flow $\sim 4 \text{ cm/s}$

maximal drift time for positive ions: 2 s $\rightarrow$ flow carries $8 \text{ cm} \dots$

total length $\sim 10 \text{ cm}$ $\rightarrow$ collision time constant $\sim 0.5 \text{ sec}$ (2 cm)

Hole Attachment Kinematics:

k_+ : reaction constant for charge transfer from hole to molecule/atom;
change in number n_{Rn} of Rn atoms in a hole concentration n_h :

$$dn_{\text{Rn}} = -n_h k_+ n_{\text{Rn}} dt$$

solution: $n_{\text{Rn}}(t) = n_0 \exp(-k_+ n_h t) \rightarrow$ time constant: $\tau = 1/(k_+ n_h)$

little known in IXe; guidance from measurements in other materials
($\text{CCl}_4^+ \rightarrow \text{C}_n\text{H}_m^+$ in different liquid alkanes...):

$\rightarrow k_+ \sim 1\text{e-}11\text{cm}^3/\text{s}$ from before: $\tau < 0.5\text{s}$ (2cm flow)

$\rightarrow n_h > 1/(k_+ \tau) = 2\text{e}11/\text{cm}^3$

A Possible Layout:

first idea:
gamma source
in anode?!

gamma
conversion
volume

Gamma source advantages:
no windows
(transparency...)
failsafe!!!

Cul-de-sac: (french for dead end)

transit
volume

impurity
collection
volume

Creating e^-/h^+ Pairs in Liquid Xenon

Hole drift: $\sim 10\text{cm/s}$ @ 3kV/cm ; we need $2e^{11}h^+/\text{cm}^3$

→ need to produce $2e^{12}h^+/\text{s/cm}^2$

mean energy required to produce e^-/h^+ pair: $W = 15.4\text{eV}$

^{55}Fe : $6\text{keV} / 15\text{eV} = 400 h^+$

→ $\sim 5\text{GBq}$

^{207}Bi : $1.6\text{MeV}/15\text{eV} = 110,000 h^+$

→ $\sim 18\text{MBq}$

IF all go into 1cm^2 ...

Conclusion: not workable!

Solution: Hole injection by field emission; done in IAr & IXe:
IEEE Transactions Vol. EI-19, Feb. 1984; Arie + Schmidt

Hole Injection in IXe:

From: IEEE Transactions on Electrical Insulation Vol. EI-19, Feb 1984
K. Arii & W.F. Schmidt: Current Injection and Light Emission in Liquid Argon and Xenon in a Divergent Electric Field

problem with article above: "... A quantitative evaluation of our data is not possible since no control existed over the geometry of the tip and its change during the injection process."

but: the principle is okay !!!

→ hole injection by field emission from tip,
→ resulting current stable.

last time: need $2 \times 10^{12} \text{h}^+/\text{cm}^2/\text{s}$; 40cm^2 (later)
→ $\sim 10^{14} \text{h}^+/\text{s} = 16 \mu\text{A}$; $1.6 \times 10^{-9} \text{A}/\text{tip} \rightarrow 10000 \text{tips}$

**Q: uniform hole current
over all volume ???**

Pics from SNU, Seoul, Korea:

Figure 1 Copper micro-tips formed by high current pulse electroplating. (a) Top view, (b) Cross view

Field Emission Characteristics of Carbon Nanocoils Grown on Copper Micro-tips
W.Y. Sung, W.J. Kim, S.C. Yeon, S.M. Lee, H.Y.lee, Y.H. Kim ← in contact

Monitoring:

Cathode
current =
hole current

Summary:

- drifting complicated molecules and simple atoms in both LXe and LAr proven and measured
- injecting both holes (positive charges) and electrons into both LXe and LAr proven and measured

conclusion:

- method to “move” impurities (electronegative = very easy...) from main liquid(!) circulation stream to smaller secondary stream for further treatment (e.g. evaporation and hot getter)
- questions:
 - can Korean Cu micro-tips be replicated?
 - are they stable over time under operating conditions

note: electrons can be generated by shining UV on metal...
that alone could take care of electronegative impurities
