Stellar-mass black holes in star clusters: gravitational waves and the "dark cluster remnants"

Sambaran Banerjee

Argelander-Institut für Astronomie, University of Bonn, Germany With. Holger Baumgardt (Univ. Queensland, Australia) Pavel Kroupa (AlfA, Univ. Bonn)

Parallel session: "Gravitational waves" 25th Symposium on Relativistic Astrophysics (TEXAS 2010) December 6-10, 2010, Heidelberg, Germany

Stellar-mass black holes in star clusters

- Black Holes (BH) in star clusters form in early evolutionary phase (~ 10 Myr) through supernovae of ≥20M_☉ stars — stellar mass BHs ~ 10M_☉ (for low metallicity clusters).
- Evidences from recent X-ray observations several Globular Cluster (GC) BH-candidates, *e.g.*, NGC4472 X-ray source, Maccarone et al. 2007; CHANDRA candidates, Brassington et al. 2010; ULX systems (likely stellar BH-WD candidates, Ivanova et al 2010).
- Dynamically significant: Mass-stratification/Spitzer instability *pure BH-core formation* due to runaway sinking.
- Potential consequences: dynamical formation of tight BH-BH binaries — promising sources of GW for ground-based detectors; modification of dynamical evolution.
- BH-normal star encounters: potential formation of BH X-ray binaries.

Gravitational waves from star clusters

Dynamical BH - BH binaries

How BH - BH binaries form from a population of single BHs?

• In *close encounter among three BHs*, two get bound as third escaping BH carries away excess K.E.

 $BH + BH + BH \longrightarrow (BH + BH) + BH$

 Multiple exchanges — BHs being more massive replace binary members in successive exchange encounters (important when primordial binaries present).

> $(S + S) + BH \longrightarrow (S + BH) + S$ $(S + BH) + BH \longrightarrow (BH + BH) + S$

N-body computations

- Concentrated *Plummer clusters* of single stars with $r_h(0) \le 1.0 \text{ pc}$, $N(0) \le 10^5 \text{ low-mass}$ $(0.5M_{\odot} \le m \le 1.0M_{\odot})$ stars.
- $M_{BH} = 10 M_{\odot}$ BHs added with same distribution as stars — the number N_{BH} of BHs added consistent with a Kroupa IMF with full/half retention fraction.
- Isolated clusters without primordial binaries BHs mostly unaffected by tidal field.
- BH-BH binary evolution due to GW radiation using *Peters'* formula: applied for *individual* binaries and *hierarchies*.
- GW emission-recoil during final merger phase likely to eject merged BH *arbitrary large velocity kick* \sim 100 Km s⁻¹ *applied* to eject merged BH from cluster.
- All computations using state-of-the-art NB0DY6 direct N-body integrator (Sverre Aarseth) on GPUs.

Can dynamical BH-binaries merge via GW?

Dynamical BH-BH binaries shrink due to *encounter hardening* (Heggie's law). • BH hardening

Few BH-binaries near $T_{mrg} = 10 \text{ Myr}$ *line* — "potential" candidates for mergers. Typical for simulations with medium to large *N*.

Which clusters are best candidates?

We infer,

- (a) Concentrated star clusters with N(0) ≥ 5.0 × 10⁴ and significant BH-retention produce dynamical BH-BH binaries that merge within Hubble time.
- (b) Most mergers occur within first few Gyr cluster evolution (for both in-cluster & escaped BH-binaries).
 Merger time dist.

Star clusters with *initial mass* $M_{cl}(0) \gtrsim 3 \times 10^4 M_{\odot}$ that are few Gyr old seem best candidates — represent Intermediate-age Massive Clusters (IMC). • Cluster MF

BH-BH merger Detection rate

Dark remnants

Which clusters are best candidates? (cont)

- GCs too old (~ 10 Gyr): most BH-BH pairs already merged.
- Young massive clusters (age < 50 Myr) are *too young*. Generally mergers happen much later.

IMCs appear most likely candidates for dynamically forming present-day BH-BH mergers.

Summary

(日) (日) (日) (日) (日) (日)

Heating of cluster core: effect of metallicity

Ejected BHs returning to core via dynamical friction deposit K.E. in central region — *expansion of cluster core*.

Lower Z yields more massive BHs, hence core expansion stronger.

Also, lower Z tends to produce more BH-BH mergers: low Z computation: 3 mergers within Hubble time; high Z computation: 1 merger [Work in progress, also see Mackey et al. (2008)] Stellar-mass BHs in star clusters

BH-BH merger Detection rate

Dark remnants

BH-BH merger Detection rate

Total LIGO/AdLIGO detection rate of BH-BH mergers from IMCs

$$\mathscr{R}_{\rm GW} = \frac{4}{3} \pi D^3 \rho_{cl} \mathscr{R}_{mrg}. \tag{1}$$

D = max. distance for compact-binary inspiral detection. For $10M_{\odot}$ BH-pair $D \approx 1500$ Mpc (AdLIGO). $\rho_{cl} \approx 1.4 \text{ Mpc}^{-3}$ (density of young populous clusters, Portegies Zwart & McMillan (2000)). Range Runs

- Isolated clusters with full BH retention and *power-law IMC mass* function with index = -2 (ICMF in spiral/starburst galaxies) $\Rightarrow \mathscr{R}_{AdLIGO} \approx 31(\pm 7) \text{ yr}^{-1}$
- Dynamical BH-BH binaries may constitute dominant contribution to stellar mass BH-BH merger events in the Universe.
- See Banerjee, S., Baumgardt, H. and Kroupa, P., 2010, MNRAS, 402, 371 for further details.

▶ MC Age-r_c

The "dark cluster remnants"

- The BH-core depletes in $\tau_{BH} \sim 700 1000 \text{ Myr}$ through ejections due to dynamical encounters (O'Leary et al. 2006, Banerjee et al. 2010).
- Galactic tidal field preferentially remove low-mass stars and retain heavier BHs (also neutron stars).
- Rapid tidal dissolution close to Galactic center in timescale shorter or comparable to τ_{BH} form cluster remnants containing few stars orbiting around a cluster of BHs.
- Observationally appear as highly super-virial or large mass-to-light ratio star clusters bound by invisible mass: the "dark cluster remnants".
- Comprise predicted new class of objects.
- Their existence implies significant survival of BHs in star clusters following formation via supernovae — constraint on supernova natal kicks. (Banerjee, S. & Kroupa, P., in preparation)

Black hole binaries

Detection rate

Dark remnants

Lifetime of dark cluster remnants: estimated population

 $\label{eq:lifetime} \begin{array}{l} \mbox{Lifetime in remnant phase} \\ \sim 100 \mbox{ Myr } (Q_* > 1.0), \mbox{ about twice for } Q_* > 0.75. \end{array}$

Plausible parameter range for remnant formation: $M_{cl}(0) \gtrsim 10^4 M_{\odot}, R_G \lesssim 5$ Kpc (taking full NS/BH retention).

Estimated present population ($R_G \leq 5$ Kpc): $N_{rem} \approx 50/80(Q_* > 1.0/0.75)$. Assuming uniform average cluster formation $0.16M_{\odot}$ yr⁻¹ & Schechter cluster mass function (see, *e.g.*, Larsen 2008).

Stellar-mass BHs

Summary

Gravitational waves from star clusters:

- BH-only subcluster dynamically potential for a wide variety of physical phenomena — GW emission, cluster core expansion, formation of BH X-ray binaries.
- Star clusters with *initial* mass $M_{cl}(0) \gtrsim 3 \times 10^4 M_{\odot}$ dynamically produce BH-BH mergers (inside cluster or escaped) within *few Gyr*.
- IMCs seem best candidates for present-day BH-binary mergers.
- Preliminary estimate of merger rate for "AdLIGO" \approx 30 yr⁻¹ dynamical BH-BH merger might dominate stellar mass BH-BH merger events in the Universe.

Dark cluster remnants:

- Rapid tidal stripping of stars from clusters close to Galactic center results remnants that appear highly super-virial clusters bound by unseen mass — predicted new type of objects.
- Can form as remnants of initially M_{cl}(0) ≥ 10⁴ M_☉ clusters within R_G ~ 5 Kpc Galactocentric distance (taking full NS/BH retention) — expected in significant numbers (N_{rem} ~ 50).
- Detection can provide constraint on supernova natal kicks.

Summary

N-body computations: reflective boundary

- Star-clusters confined within perfectly reflecting sphere.
- *Mimics only core* of a cluster.
- Fewer stars needed, much faster than full cluster computation: we use N = 3000 4000 stars within $R_s = 0.4$ pc giving $\rho \sim 10^4 M_{\odot}$ pc⁻³.
- Stars faster than v_{esc} ≈ 24 Km s⁻¹ allowed to escape
 inhibits runaway heating.

BH depletion

Maximum distance for GW inspiral detection

The range of detection of GW from inspiralling compact binary:

$$D = D_0 \left(\frac{M_{ch}}{M_{ch,nsns}}\right)^{5/6},$$
 (2)

 $\textit{D}_{0} \approx 300$ Mpc (AdLIGO) ≈ 18 Mpc (LIGO).

 $M_{ch} \Rightarrow$ "chirp mass" for component masses m_1 , m_2 :

$$M_{ch} = \frac{(m_1 m_2)^{3/5}}{(m_1 + m_2)^{1/5}},$$
(3)

and $M_{ch,nsns} = 1.2 M_{\odot}$ for a NS-NS binary. For BH-BH pair $M_{ch} = 8.7 M_{\odot}$.
